Abstract

A field experiment was conducted at the Pulse Research Centre of Bangladesh Agricultural Research Institute, Ishurdi, Pabna during Kharif-II season of 2010 to evaluate the efficacy of five herbicides for controlling weeds associated with mungbean (BARI Mung-6). The five herbicides such were; Paraxon (27.6% WV Paraquat dichloride salt), M-clor 5G (Butaclor), Topstar 40 WP (40% Oxadiargyl), Hammer 24 EC (Carfentrazone ethyl), and Panida 33 EC (Pendimethalin) with one control (no herbicide and also no weeding). Weed was collected species wise during weeding at 40 days after sowing from 1 m² area of each plot and oven dried to estimate weed growth. Among the herbicides, Panida performed the best for reducing the number and dry weight of weeds. The maximum reduction of weed population, the highest weed control efficiency, seed yield (1222 kg ha⁻¹), and maximum economic benefit were also obtained in the treatment receiving Panida 33 EC @ 2 ml L⁻¹.

Keywords: Herbicides, efficacy, controlling weeds, mungbean

1. Introduction

Mungbean (Vigna radiata L. Wilczek) is the second most important pulse crop grown in Bangladesh in respect of acreage and production. It covered an area of 35203 hectares with annual production of 25,000 metric tons during 2012-2013 growing season (BBS, 2014). It is a nutritious food item with high content of protein (20-25%), minerals (4%) and carbohydrate (46-51%) (BARI, 2008). Due to rapid growth and early maturity, the crop fit well in rice-based cropping system, resulting in the increase of small landholders’ income and improvement of soil fertility (Nsoukpo-Kossi et al., 1999).

However, one of the major constraints in mungbean production is weed competition. The loss of mungbean yield due to weeds ranges from 65.4% to 79.0% (Shuaib, 2001; Dungarwal et al., 2003). Besides causing crop losses, weeds creating competition for nutrients, space, water etc. reduce the crop yield and the quality of produce hence; reduce the market value of the turnout (Arif et al., 2006). As most mungbean is sown as broadcast, it is difficult to weed them and therefore, farmers do not weed at all in the mungbean field. In most cases, one to two weeding are necessary. For the success of summer production of mungbean in Bangladesh, the role of weeding needs to be emphasized (FAO/UNDP, 1984). Weed competition with mungbean persisting for 20-30 days after emergence was very critical and prolonged competition resulted in substantial yield reduction (Naeem et al., 1999). There are
different weed control methods like manual, mechanical and chemical (herbicide) etc. But manual and mechanical weeding are laborious, time consuming and costly. Today, some herbicides are available in the market which is capable to control weeds in crop fields. Weed competition is maximal during the early stage of growth. However, the most critical period of weed competition varies with the growth behavior of the crop variety, environmental conditions, stage of growth, weed species presence and intensity of weed infestation.

Weed control is a major problem in legumes, because of slow growth of seedlings and hence most of the fast growing weeds smother pulse crops. Weed competition is very severe during rainy period, particularly at early stages (30 to 45 days after sowing) of the legume crops and hence early weed control is essential. Herbicides inhibit weed growth for considerable period after their application as reported by Gupta (2003). But little information is available regarding the herbicide(s) that is actually suitable for either pre-sowing or post-sowing application in mungbean. Therefore, the present research work was carried out to find out the suitable herbicides for controlling weeds associated with mungbean by pre or post-sowing application and to evaluate the relative efficacy of herbicides on growth, yield and profitability of mungbean.

2. Materials and Methods

The field experiment was conducted at research farm of Pulse Research Centre of Bangladesh Agricultural Research Institute, Ishurdi, Pabna during Kharif-II season of 2010. The trial consisted of six herbicides such as T₁ = Paraxon (27.6% WV paraquat dichloride salt) @ 2.0 ml L⁻¹ water, T₂ = M-clor 5G (Butaclor) @ 2.5 g L⁻¹ water, T₃ = Topstar 40 WP (40% Oxadiargyl) @ 1.0 g L⁻¹ water, T₄ = Hammer 24 EC (Carfentrazone ethyl) @ 1.0 ml L⁻¹ water, T₅ = Panida 33 EC (Gluphosinate-ammonia) @ 2.0 ml L⁻¹ water, and T₆ = unweeded control. The experiment was laid out in randomized complete block design with 3 replications. The unit plot size was 5 m×4 m. Seeds were sown on the 26 August, 2010. The variety BARI mung-6 was grown with a fertilizer dose @ 20:40:20 kg ha⁻¹ of N:P₂O₅:K₂O in the form of urea, single superphosphate, muriate of potash, respectively as basal application during final land preparation. The seeds were sown @ 25 kg ha⁻¹ in furrows at 30 cm x 10 cm spacing at a depth of 2 to 3 cm below the soil surface. Herbicides were applied in two leaf stage of mungbean as dose mentioned in treatment.

Two irrigations were applied, one at immediately after seed sowing and another at flowering stage (35 DAS) of crop. Intercultural operations such as mulching, thinning, applying insecticides were done as and when necessary. Weed samples were taken at 40 DAS from 1 m² area in each plot using quadrate and weed population and dry weights were recorded. The pod of mungbean was harvested twice at 21 October and again at 9 November, 2009, respectively. The crop growth, weed dry weight and weed control efficiency were recorded at 40 days after sowing of the crop. Weed control efficiency (WCE %) and intensity of weed infestation were calculated following Kundu et al. (2009) as:

\[
WCE = \frac{X - Y}{X} \times 100
\]

Where, \(X\) = Number or dry weight of weeds in unweeded plot and \(Y\) = Number or dry weight of weeds in treated plot.

Intensity infestation = \[
\frac{\text{Absolute density of a given weed species/unit area (m}^2\text{)}}{\text{Absolute density of the crop plant/unit area (m}^2\text{)}}
\]

Data on yield and yield contributing characters were recorded from five randomly selected plants from each plot and grain yield (kg ha⁻¹) was recorded from the whole plot. Data were statistically analyzed using MSTAT-C program and the treatment means were compared using LSD at 5% by Duncan’s Multiple Range Test (DMRT) according to Gomez and Gomez (1984). All types of variable production cost were recorded to find out the cost and return.
Economic analysis with respect to gross margin was calculated to evaluate the profitability of different treatments.

3. Results and Discussion

3.1. Grain yield and yield components

Yield and yield contributing characters of mungbean varied significantly due to the application of herbicides (Table 1). The tallest plants (52.53 cm) were obtained from T5 and the height was minimal (40.13 cm) in unweeded control treatment (T6) as weed suppressed the growth of mungbean plants. Different weed control methods significantly affected plant height of mungbean as reported by Chattha et al. (2006). Number of pods per plant among the herbicidal treatments was statistically similar but unweeded control produced the least. Chattha et al. (2006) observed that the number of pods per plant was significantly affected by different weed control methods. Seeds per pod and 1000-seed weight are varietal characters and hence did not differ significantly among the herbicides used as treatment.

The height seed yield (1222 kg ha\(^{-1}\)) was obtained from T5 followed by T2 (1088 kg ha\(^{-1}\)). The yield produced in the treatments T5 (962.7 kg ha\(^{-1}\)), T1 (906.7 kg ha\(^{-1}\)), and T4 (883.3 kg ha\(^{-1}\)) did not differ statistically. Application of Weedicides might control the growth of weeds that facilitated proper crop growth led to produce higher yields. The lowest seed yield (741.7 kg ha\(^{-1}\)) was recorded in unweeded control plot (T6) might be due to the weed infestation disturbed proper utilization of growth resources by the crop plants. The highest yield increment (65%) over the unweeded control was recorded in Panida applied plot followed by M-Clor (47%). The increment was 30% in Topstar, 23% in Paraxon and Hammer the least (19%). Weed infestation in mungbean is one of the main causes of low yield per hectare against the potential yield and uncontrolled weeds can reduce mungbean yield by 46, 69 and 35% as reported by Pandey et al. (2003), Yadav et al. (2005) and Raman et al. (2005), respectively.

3.2. Effect of herbicide on weed population and weed dry weight

Different weedicides reduced the growth of weeds in mungbean. The highest weed population (900) was recorded in unweeded control treatment (Fig. 1) which resulted the highest dry matter production (Fig. 2) might be due to the unchecked growth of weeds at all stages of crop growth. Among the different herbicides, the highest weed population (754) was counted in Hammer applied plot which was statistically similar with Topstar (741) and Paraxon (738). The lowest population (592) was observed in the plots where Panida was applied. Significant differences due to weed control treatments were recorded in weed biomass. The dry matter weight by the application of Hammer, Topstar, Paraxon and M-clor were 243, 239, 238 and 231 g m\(^{-2}\), respectively but Panida was the lowest (191 g m\(^{-2}\)). According to Bhanumurthy and Subramanian (1989) weed dry matter is a better parameter to measure the competition than the weed number. The percentage of reduction in weed dry weight per m\(^2\) did not differ among Hammer (16.20%), Topstar (17.58%) and Paraxon (17.93%) but Panida performed better by reducing 34.13% dry weight over the unweeded control treatment.

Price: Urea= Tk. 6.00 kg\(^{-1}\), TSP= Tk. 47.00 kg\(^{-1}\), MOP= Tk. 37.00 kg\(^{-1}\), Labour = Tk. 120.00 per man-day, Mungbean seed = Tk. 80.00 kg\(^{-1}\)

3.3. Weed control efficiency (%) and intensity of weed infestation

Weed control efficiency of herbicides and intensity of infestation of weeds have been presented in Table 2. The highest weed control efficiency (34.13%) was found in T5 (Panida) and the lowest efficiency (16.20%) was recorded in T4 (Hammer). Meanwhile, the lowest intensity of infestation (20.93) was recorded in T5 (Panida) and the highest (27.83) was in T4 (Hammer).

3.4. Economics

Total variable cost varied among the treatments due to the addition of price of herbicides, its application cost and cost of additional yield harvest (Table 3). The total variable cost was the lowest in unweeded control. The highest gross return was calculated in the treatment T5 (Tk. 97760 ha\(^{-1}\)) followed by T2 (Tk. 87040 ha\(^{-1}\)) and T3 (Tk. 77016 ha\(^{-1}\)). The lowest return was in control T6 (Tk. 59336 ha\(^{-1}\)). Similar trend was also observed in case of gross margin in treatment T5 (Tk. 58490 ha\(^{-1}\)).

4. Conclusions

Weed population, weed biomass and seed yield of mungbean differed significantly due to chemical weed control treatments. The performance of other herbicides except Panida seemed to be identical in controlling weeds that infested the mungbean field. The highest weed control efficiency and the lowest weed infestation were observed in Panida applied plot.
This treatment (T5) out yielded other treatments in terms of number of pods per plant, number of seeds per pod, 1000 grain weight, grain yield and net benefit. Therefore, application of Panida in mungbean field seems to be promising in keeping the field weed free during the critical growth period and ensuring higher seed yield.
