ABSTRACT

Among hospitalized patients, the most common nosocomial infection is Urinary tract infection (UTI). The knowledge about the type of pathogens responsible for UTI and susceptibility and resistance pattern of the causative agents at a specific area may help the doctors to choose correct treatment regimen. This study was aimed to investigate the antibiotic susceptibility and resistance pattern of isolated urinary pathogens. This study was done at Anwer Khan Modern Medical College Hospital, Dhaka during January- June, 2011. Out of 498 clinical samples of urine collected, 245 (49.19%) showed significant bacterial growth. The most common pathogens isolated were Escherichia coli (142, 58.0%), Streptococcus faecalis (38, 15.5%), Pseudomonas (20, 8.2%), Klebsiella species (20, 8.2%) and Staphylococcus epidermidis (14, 5.7%). Members of the Enterobacteriaceae were 75%-100% sensitive to Amikacin and Nitrofurantoin while they were found variably sensitive to other commonly used antibiotics. Pseudomonas species were found 90% sensitive to Meropenem and 70% to Amikacin. Strep. faecalis were found 94.7% sensitive to Amoxicillin, 84.2% to Amoxiclave and 78.9% to Ciprofloxacin, 65.5% to Cephalexin, 50% to Ceftriaxone. The clinicians should use Meropenem and Amikacin selectively in cases of un-responsiveness to commonly used antibiotics.

Key words: Urinary tract infection, Nosocomial infection, Escherichia coli, Klebsiella species

Introduction

Urinary tract infection (UTI) is one of the most important causes of morbidity in the general population, and is the second most common cause of morbidity among hospital visitors. Moreover, UTI was found as the most common causes of nosocomial infection among hospitalized patients. With advancing age, the incidence of UTI increases in men due to prostate enlargement and neurogenic bladder. Recurrent UTI are common and can lead to irreversible damage to the kidneys, resulting in renal hypertension and renal failure in server cases. In the community, women are more prone to develop UTI. It has been observed that about 20% of the women experienced a single episode of UTI during their lifetime, and 3% of women had more than one episode of UTI per year. Pregnancy also makes the women more susceptible to the infection. Catheter-associated UTI is a trenchant problem with about 10% of the patients developing bacteriuria.
Isolation of Bacteria Causing Urinary Tract Infections and their Antibiotic Bacteriuria. Antibiotic susceptibility test was carried out by the Kirby Bauer technique and interpretations were made for each bacterial isolate following interpretative criteria recommended by the National Committee for Clinical Laboratory Standards (NCCLS). Appropriate quality control strains were used to validate the results of the antimicrobial disk. The following were the quality control strains used: Pseudomonas species NCTC-10662, Staphylococcus aureus NCTC-6571, Escherichia coli NCTC-10418.

Results
Out of 498 samples of urine, 245 (49.19%) showed significant growth of uropathogens. Considering age distribution of the culture-positive case, 49 (20.0%) were children aged 10 years of less, and 64 (26.1%) were aged 41-60 years. In all age groups, females were more frequently affected than males. (Table I)

The commonest organisms isolated were Escherichia coli (142, 58.0%) and Str. fea (38, 15.5%), Pseudomonas species (20, 8.2%), Klebsiella species (20, 8.2%) and others including Coagulase-negative Staphylococcus (14, 5.7%). (Table II)
E. coli and Klebsiella were found highly sensitive to Amikacin and Nitrofurantoin, but almost all were resistant to Amoxiclav, Amoxicillin, Gentamicin and Ceftriaxon, and variably sensitive to Ceftriaxon, Ceftazidime, Meropenem and Cipofloxacin.

Proteus species were 100% sensitive to Ceftriaxon, Ceftazidime, Cefixime, Ciprofloxacin, Amikacin and 75% to Meropenem and Nitrofurantoin, while 100% of them were resistant to Amoxicillin and 50% to Co-trimoxazole, Cephalxin, Cephradin (Tables IIIa and IIb).

Pseudomonas species were found 90% sensitive to Meropenem and 70% to Amikacin, while 100% of the organism were resistant to Co-trimoxazole,Cephalxin, Cephradin; 95% to Amoxicillin; 80% to Carbencillin; 75% to Ceftriaxon; 60% to Ceftazidim and Cefixime; 55% to Nitrofurantoin; 45% to Ciprofloxacin. (Tables IIIa and IIb)

Staph. saprophyticus were 100% sensitive to Co-trimoxazole, Cephradin, Ciprofloxacin, Amikacin while 100% were resistant to Amoxicillin, Cephalxin, Cefixime, Ceftraxon. (Tables IIIa and IIb)

Citrobacter were 100% sensitive to Ceftriaxon, Ceftazidim, Ciprofloxacin, Amikacin and 66.7% to Cefixime, Nitrofurantoin while 100% were resistant to Amoxicillin, Co-trimoxazole, Cephradin. (Tables IIIa and IIb)

Strep. feacalis were found 94.7% sensitive to Amoxicillin, 84.2% to Amoxiclav and 78.9% to Ciprofloxacin, 65.5% to Cephalixin, 50% to Ceftriaxon and 97.4% resistant to Co-trimoxazole, 92.1% to Gentamicinc, 68.4% to Cephradin, 52.6% to Cefixime. (Tables IIIa and IIb)

Staph. epidermis was 85.7% sensitive to Amoxicillin and Cephradin each, 71.4% to Cephalixin, 50% to Amoxiclav, while variably resistant to Co-trimoxazole, Ceftriaxon, Ciprofloxacin, Cefixime and Gentamicin. (Table IIIa and IIb)
Identification of the uropathogens and their susceptibility pattern is very important in treating the cases of Urinary Tract Infections (UTI). In the present study, urine specimens were cultured to see pattern of uropathogens and some 245 (49.19%) of the urine showed significant growth of bacteria. So, majority (50.81%) of the cases remaining showed either insignificant bacteriuria or no growth with urine from the suspected cases of UTI. Prior antibiotic therapy before submitting the urine samples, and clinical conditions like non-gonococcal urethritis or others that mimic UTI could be that factors responsible for insignificant bacteriuria or no growth of Coagulase-negative Staphylococcus which are supposed to be non-pathogenic. This indicates the need for educating the patients about the method of collection of clean catch mid-stream urine specimens.

The age and sex distribution of the patients diagnosed with UTI among the hospitalized patients and those attending the outpatient department followed the natural epidemiological pattern of UTI. There was a predominance of young and middle aged females, whereas in the children and younger age groups, almost equal proportions of male and females had UTI.

In the present study, the most common pathogens isolate was Escherichia coli-58.0%, followed by Strep. feacalis-15.5%, Klebsiella & Pseudomonous species-8.2%, Staphylococcus epidermidis (5.7%), Proteus species (1.6%), Acenatobacter & Citrobacter (1.2%) and Staphylococcus saprophyticus (0.4%). The isolation rate of urinary pathogens of the present study is consistent with reports of other studies published elsewhere recently15,16. E. coli was the principal pathogen isolated showing a high susceptibility to Amikacin (95.8%), Nitrofurantoin (92.3%), but showed variable sensitivity to other commonly used antibiotics. This is consistent with reports from different countries who have reported an increasing resistance to Amoxicillin, Ciprofloxacin, and Ceftriaxone19,16,17. Another study from Bangladesh reported and increases resistance of the uropathogens to Ciprofloxacin10.

In the present study, Klebsiella species also showed high susceptibility to Amikacin (95.0%) and Nitrofurantoin (80.0%), but were relatively resistant to commonly used antibiotics. Proteus species were 100% sensitive to Ceftriaxone, Ceftazidime, Cefixime, Ciprofloxacin, Amikacin and 75% to Meropenem and Nitrofurantoin. This finding is comparable with Manjula et al of India, who found members of Enterobacteriaceae variably sensitive to Amoxiclav, Ceftriazone, Ceftazidmice and Ciprofloxacin but found all isolates sensitive to Imipenem. Similar susceptibility pattern were also reported by other investigators19.

Pseudomonas species, a common cause of hospital-acquired UTI, was found less sensitive to the common antibiotics but sensitive to Meropenem (90%) and Amikacin (70%).

Similar results were reported by investigators from other countries\textsuperscript{16,20}. Pseudomonas species were relatively susceptible to the second line of anti-pseudomonas drugs and most of these were associated with high-level resistance to the first-line antibiotics investigated namely Amoxiclav, Ceftriaxone, Ciprofloxacin and Gentamicin. This may be due to widespread use of common antibiotics in the hospital and cross-resistance among different bacteria.

The results of the present study showed that sensitivity rate of the ruopathogens were low for Co-trimoxazole and Amoxicillin. This low sensitivity could be due to widespread use of the antibiotics in the community. It is possible that the low sensitivity is present among uropathogens of the nosocomial as well as community-acquired UTI. The patients attending outpatient department and some of the hospitalized patients may be having community-acquired UTI. In the present study, community-acquired UTI. In the present study, community-acquired UTI and nosocomial UTI were not been distinguished. This was the main limitation of the study.

A high isolation rate of pathogens from urine samples of clinically suspected UTI shows a good correlation between clinical findings and microbiological methods. Gram-negative bacteria were the commonest organism isolated, among which E.coli was the principal urinary.
