Pattern of Pulmonary Function Test in Patients with Severe Mitral Stenosis

Umme Salma Khan⁴, Abdullah-Al-Shafi Majumder², A K M Monwarul Islam³, Fazle Rabbi Mohammed⁴

Abstract:
Background: The deterioration in lung function in mitral stenosis correlates with the severity of stenotic valves. A correlation is noted between vital capacity and the severity of dyspnoea in patients with mitral stenosis. This study tried to evaluate the pattern of pulmonary function test in patient with severe mitral stenosis.

Materials & Methods: This study involving 56 patients of severe mitral stenosis was performed in a referral cardiovascular center at Dhaka, Bangladesh from January to September, 2011. Colour doppler echocardiography and pulmonary function test were performed in each cases. Forced vital capacity (FVC), forced expiratory volume in first second (FEV1), FEV1/FVC and peak expiratory flow (PEF) rate was assessed from pulmonary function test. Finally, pattern of pulmonary function test in severe mitral stenosis was assessed.

Results: Among 56 patients, 46 were female with a male female ratio 1: 0.22 and the mean age of patients was 28.76 ± 7.2. Among patients with severe mitral stenosis, mean FEV₁ (%) was 60.18 ± 13.054. Minimum FVC (%) was 26, maximum was 90 with mean 53.80 ± 12.313. The PEF varied from 150 to 330 L/minute with mean 223.75 ± 62.3251. In current study, out of 56 patients, 2 cases had obstructive type and rest of the patients had restricted type of airway on pulmonary function.

Conclusion: The brief results of this study reveal that severe mitral stenosis is associated with impaired pulmonary function, usually presenting restrictive airway pattern.

Key words: Pulmonary function test, Mitral stenosis.

Introduction:
Rheumatic mitral valvular disease is a common and major cause of cardiovascular morbidity and mortality in Bangladesh.¹ The prevalence of rheumatic heart disease was found to be 1.3 per 1000 for Doppler echocardiography – defined rheumatic heart disease.² The most useful descriptor of the severity of mitral valve obstruction is the degree of valve opening in diastole, or the mitral valve orifice area. When the orifice is reduced to 1 cm² it represents severe mitral stenosis (MS). In severe MS, a left atrioventricular pressure gradient of approximately 20 mmHg is required to maintain normal cardiac output at rest.³ Pulmonary venous pressure rises with left atrial (LA) pressure increase and is passively associated with an increase in pulmonary arterial pressure. In up to 20% patients, the pulmonary vascular resistance is also elevated which increases pulmonary artery pressure.⁴ The chronic changes in pulmonary circulation cause alterations in pulmonary vessels and in the composition of lung tissue. Accumulation of water, proteins, and proteoglycans in the interstitium has been described in this condition. These interstitial changes are the basis of the clinical manifestations of mitral stenosis and can be detected by pulmonary function tests.⁵ The deterioration in lung function in mitral stenosis correlates with the severity of stenotic valves and the severity of respiratory symptoms.⁶ A correlation is noted between vital capacity (VC) and the severity of dyspnoea in patients with mitral stenosis. It was reported that the degree of dyspnoea showed a closer relation to the height of pulmonary artery pressure and to VC, than to maximum breathing capacity in the pure mitral stenosis patients.⁷ This study tried to evaluate the pattern of pulmonary function test (PFT) in patient with severe mitral stenosis.

Material & Methods:
This observational study involving 56 patients of severe mitral stenosis was performed in a referral cardiovascular center at Dhaka, Bangladesh from January to September, 2011. Patients with severe mitral stenosis, New York Heart Association (NYHA) class II, III, and IV symptoms and age < 40 years excluding preexisting obstructive airway diseases and restrictive lung diseases, neurological disability, chest wall deformity, left ventricular ejection fraction < 50% were included in this study. Colour doppler echocardiography and pulmonary function test (PFT) were performed in each cases. Forced vital capacity (FVC), forced expiratory volume in first

When the orifice is reduced to 1 cm² it represents severe
mitral stenosis (MS). In severe MS, a left atrioventricular
pressure gradient of approximately 20 mmHg is required to
function in mitral stenosis. It was
disturbance in patients with mitral stenosis. It has been
determined that subclinical pulmonary oedema accounts for some
morphological changes that often result in well-defined
clinical correlates, such as obstructive and restrictive
abnormalities in lung function, increased bronchial
capillary.9,10

Many patients of mitral stenosis present with respiratory
symptoms, and are often treated as bronchial asthma or
chronic obstructive airway disease. Impaired pulmonary
function may be an important contributor to over all
morbidly and mortality in our country, where the patients
often present late. Here lies the rationale of the present study.

Fifty-six patients with severe mitral stenosis were enrolled in
this study. The mean age of this study subject (28.76 ± 7.2)
differed from the study done by Simkova and Urbanova in
2001.11 A comprehensive study by Yoshioka in 1990 showed
age range from 31 to 71 years.12 In current study the mean
population age is much younger than the other studies. In the
present study male and female ratio (1:0.22) differed from a
population age is much younger than the other studies. In the

Results:

Total 56 patients were enrolled in this study where 46 were
female with a male female ratio 1:0.22. The mean age of
patients was 28.76 ± 7.2.

Table-I. Distribution of the study subjects by age and sex. (n=56)

Table-I shows distribution of the study subjects according to
their age and sex. The majority of the respondents were female
46 (82.14%), and the remaining 10 (17.86%) were male. Among
the female patients, maximum were in the above 20
year age group (n=34, 60.71% of total). The majority of the
male subjects (n=8, 14.29%) were above 20 years.

Clinical characteristics | Frequency | Percentage |
------------------------|-----------|------------|
Shortness of breath     | 56        | 100.0      |
Palpitation             | 17        | 30.4       |

Table II. Distribution of patients by baseline clinical
characteristics (n = 56)

Table II shows that all the patients (n=56,100%) had shortness
of breath. Other symptoms were cough (n=29, 51.8%), chest
pain, PND, orthopnoea etc. Majority (55.4%) had history of
rheumatic fever. Among the 56 subjects, 26 (46.4%) took
prophylaxis against rheumatic fever.

Table III. Distribution of patients by pulmonary function test
(n = 56)

Table III depicts the lung function test results. Mean FEV₁ (%)
was 60.18 ± 13.054. Minimum FVC (%) was 26, maximum was 90 and mean FVC was 53.80 ± 12.313. The PEF varied from 150 to 330 L/minute with mean 223.75 ± 62.3251. In current study, out of 56 non-smoker patients, 2
cases had obstructive type and rest of the patients had
restricted type of features on pulmonary function.

Discussion:

Pulmonary congestion is a major complication of left sided
heart disease as well as left ventricular dysfunction and an
important risk factor for hospitalization. Several reports
show that in left sided heart causes, even if clinically stable,
subclinical pulmonary oedema accounts for some
morphological changes that often result in well-defined
clinical correlates, such as obstructive and restrictive
abnormalities in lung function, increased bronchial
capillary exchange across the alveolar.
blood volume, muscle fatigue, decreased lung compliance, and fibrosis from chronic congestion. In a study by Light et al. in 1983 found both obstructive and restrictive type of lesion on pulmonary function test in patients with congestive heart failure. In another study by Simkova and Urbanova (2001) found restrictive as well as obstructive ventilatory disturbance in patients with mitral stenosis. It has been speculated that weakness of the chest wall muscle limits the ability of the patients to perform the maximum expiration. Yoshioka showed all of his patients got improvement on greater part of their ventilatory function which is due to alteration of reversible pulmonary haemodynamics.

**Conclusion:**

Majority of the patients with severe Mitral stenosis demonstrated a pulmonary function limitation of restrictive type. As the respiratory symptoms are most common presenting feature of these patients, the knowledge about the pattern of limitation would help to understand the pathology better. The degree of valvular pathology correlated to PFT limitation and pattern may shed further light on the point of change in the lung pathology from a reversible to an irreversible stage. The proper timing of intervention may be also aided by the assessment of PFT. Further research is need in this field.
