SUICIDE AND SCHIZOPHRENIA

Ahmad M¹, Ali M²

The word suicide has been derived from Latin word –suicidium (su i caedere), means "to kill oneself". It is the 10th leading cause of death worldwide involving death of 8,00,000 people each year¹. Rates are three to four times higher in men than in women². There are an estimated 10 to 20 million non-fatal attempted suicides every year³.

Mental disorders are often present at the time of suicide with estimates ranging from 27% to 90%⁴. Patients, who have been admitted to a psychiatric unit, have a lifetime risk of completed suicide (8.6%). Half of all people who die by suicide have major depressive disorder; like schizophrenia, personality disorders, bipolar disorder, posttraumatic stress disorder, eating disorders etc. Approximately 20% of suicides have had a previous attempt and of that 1% complete suicide within a year and more than 5% commit suicide after 10 years. Presence of self-injurious behaviour is related to increase suicide risk. Individuals who are at risk for suicide are more likely to make an attempt, when they have command auditory hallucinations⁵.

There is no known underlying pathophysiology for either suicide or depression. It is however believed to result from interplay of behavioural, socio-environmental and psychiatric factors. Low levels of brain-derived neurotrophic factor (BDNF) is directly associated with suicide⁶ and indirectly associated through its role in major depression, post-traumatic stress disorder, schizophrenia and obsessive–compulsive disorder⁷.

Biological contributors to suicidal behaviour in schizophrenia have been examined via family history, monoamine metabolites in cerebrospinal fluid (CSF), candidate gene allele variants. Family history was found to be associated with suicidal behaviour across diagnostic groups⁸. Serotonin and norepinephrine have been the primary neurotransmitters investigated in suicidal behaviour. CSF metabolites like homovanillic acid and 3-methoxy-4-hydroxy-phenylglycol have not differentiated suicidal and nonsuicidal individuals with schizophrenia⁹–¹². but CSF 5-hydroxyindole acetic acid (5-HIAA) has been found to relate to suicide intention and lethality in patients with schizophrenia who attempt suicide¹³–¹⁴.

Forensic Pathologists performed Post-mortem studies have found reduced levels of brain derived neurotrophic factors (BDNF) in the hippocampus and prefrontal cortex, in those with psychiatric conditions¹⁵. Serotonin, a brain neurotransmitter, is believed to be low in those who commit suicide. This is partly based on evidence of increased levels of 5-HT2A receptors found after death¹⁶. Epigenetics, the study of changes in genetic expression in response to environmental factors is also believed to play a role in determining suicide risk¹⁷. Treatment with medication and cognitive-behavioral therapy (CBT) reduces suicidal behavior¹⁸. Some investigators suggest that treatment with new generation antipsychotics, clozapine and olanzapine have been found to reduce suicidal behavior in those with schizophrenia¹⁹.

“Psychosocial factors related to attempted suicide in schizophrenic patients” by Islam MM et al in this issue of JAFMC is a time worthy work. We believe that this publication will enrich our knowledge and encourage others to perform more studies in future on this subject, based on our countries perspective and considering more variables of data like sociodemographic: gender, ethnicity, religion, civil status, children, employment, social class; family history: psychiatric disorder, depression, alcohol misuse, suicide; personal history: childhood broken home/parental loss, education, IQ, living circumstances, recent loss and life events; clinical history: positive symptoms of schizophrenia, delusions, hallucinations (command), paranoia, suspiciousness, negative symptoms of schizophrenia,
flat affect, social withdrawal, agitation/motor restlessness, worthlessness/low self-esteem, hopelessness, sleep disturbance, insight, fear of mental disintegration, medication, adherence to treatment, compulsory admission, attempted suicide, suicide threats or ideation, depression (past and recent), alcohol misuse /dependence, drug misuse /dependence, substance misuse/dependence (drugs and/or alcohol), violence, impulsivity, hostility, suspiciousness, anxiety, social relationships and physical illness etc.
