Keywords: Planting technique, rapeseed, mustard, yield

Abstract

The experiment was conducted at Sher-e-Bangla Agricultural University farm to evaluate the performance of five rapeseed and mustard varieties under two different planting techniques. The planting techniques were as conventional sowing and sowing seeds in puddle soil that assigned to the main plot and five varieties viz. Improved Tori-7, BARI Sarisha -13, BARI Sarisha -15, BARI Sarisha -16 and SAU SR-3 in the sub-plots. Almost all the studied parameters were found statistically similar under two planting techniques except siliqua length that was higher (5.51 cm) in conventional method compared to that of sowing in puddled soil (5.14 cm). The highest number of siliquae plant\(^{-1}\) (143.67) was obtained from BARI Sarisha -16 that was similar to SAU SR-03 (134.15) and Improved Tori-7 (116.90). The maximum1000-seed weight (4.35 g) was obtained from BARI Sarisha -16 under conventional planting method that was similar to BARI Sarisha -13 irrespective of planting methods. The maximum number of siliqua plant\(^{-1}\) (145.20) was found in BARI Sarisha -16 under conventional planting method that was similar to the same variety in puddle soil (142.13), SAU SR-03 in both the planting method and Improved Tori-7 in conventional method (131.20). The Improved Tori-7 variety gave the maximum seed yield (2.24 t ha\(^{-1}\)) followed by BARI Sarisha -16 (1.96 t ha\(^{-1}\)) and Improved Tori-7 variety irrespective of planting techniques.

Introduction

Rapeseed & Mustard (Brassica spp. L.) commonly known as mustard in Bangladesh, is a cool season, thermo sensitive as well as photosensitive crop (Ghosh and Chatterjee, 1988). Rapeseed and mustard is the major oilseed crop of Bangladesh both on the basis of its total cultivated area and production, respectively. The present yield of rapeseed-mustard (0.95 tha\(^{-1}\)) is very low as compared to other oilseeds growing countries in the world. The main reasons of lower yield are lack of good quality seed and inadequate adoption of improved production technologies developed by different research institutes (Miah et al., 2014). Presently, on an average, 2.3 to 2.4 million tonnes of edible oils, both in oil and seeds form, are imported in the country (Alam, 2018). The internal production of edible oil can meet up only less than one-third of the annual requirement (Mondal and Wahhab, 2001). There is a great scope of increasing yield of mustard by selecting high yielding varieties and improving management practices (Bhuiyan et al., 2008). Time of sowing is very important for rapeseed/mustard production (Rahman et al., 1988; Mondal and Islam, 1993 and Mondal et al., 1999). Sowing at proper time allows sufficient growth and development of
a crop to obtain a satisfactory yield which can be fitted in between *Aman* and *Boro* rice. Farmers mostly grow the traditional variety of Tori-7 for its shorter duration (70-80 days) but average yield only 750 kg ha⁻¹. This variety is advantageous to grow as catch crop between *Aman* and *Boro* rice with minimum input and tillage practices.

There is ample scope of replacing the traditional farmers varieties by the short duration yellow seeded variety, having yield capacity of 1.50-1.65 tha⁻¹ and can easily be grown in the Aman-Mustard - Boro cropping system with 2-3% increased oil content for yellow seed without hampering existing Boro rice cultivation. In such situation, sowing time of rapeseed and mustard should be done by late October to early November that is frequently affected by rainfall and make challenge of better productivity of the pattern. Therefore, the proposed study was undertaken to find out the suitability of alternate planting method of rapeseed and mustard to fit it in the promising and widely used cropping pattern *Aman-Mustard-Boro* of Bangladesh.

**Materials and Methods**

The experiment was conducted at the Agronomy field of Sher-e-Bangla Agricultural University, Dhaka during the period from November 2013 to June 2014. The seeds of five rapeseed and mustard varieties namely Improved Tori-7, BARI Sarisha-13, BARI Sarisha-15, BARI Sarisha-16 and SAU SR-3 were collected from Bangladesh Agricultural Research Institute (BARI), Joydebpur, Gazipur and Sher-e-Bangla Agricultural University (SAU). The land was finally leveled with leveler to ensure uniform application of water. The unit plot size was 4m x 3m. The plot was fertilized with @ 250-170-85-150-5-15 kg ha⁻¹ of urea, TSP, MoP, Gypsum, Zinc sulphate and boric acid, respectively. The whole amount of all fertilizers except urea was applied as a basal dose during final land preparation. The urea fertilizer was applied as two equal installments; as basal dose and before flowering. The treatment of puddle condition of respective plots were maintained by applying water & finally leveled. The equal amount of seeds of all varieties were sown on November 5, 2013. The spacing was maintained as 30 cm in continuous soil line.

The experiment was laid out in a split-plot design with three replications. Two planting techniques namely conventional (P₁) and Puddle soil (P₂) were assigned in the main plot and five varieties viz., Improved Tori-7 (V₁), BARI Sarisha-13 (V₂), BARI Sarisha-15 (V₃), BARI Sarisha-16 (V₄) and SAU SR-3 (V₅) in the sub-plot. Water was ensured to the field in such a way that there should not have any scarcity of water that affects the experiment. Two hand weedings were done for all the treatments at 15 and 25 days after sowing (DAS). The field was infested by different insects and diseases which were controlled as and when necessary. The different varieties were harvested on different dates at full maturity. The statistical analyses were done by using the Crop Stat computer package and the mean differences among the treatments were compared by least significant difference test at 5 % level of significance following Gomez and Gomez (1984).
Performance of Rapeseed and Mustard

Results and Discussion

Silica length

Effect of planting technique
The silica length was significantly differed due to planting technique (Table 1) where longer silica (5.51 cm) was found in conventional sowing compared to that of sowing in puddle soil (5.14 cm).

Effect of variety
The variety showed significant effect on silica length (Table 1). The maximum length (7.19 cm) was recorded in BARI Sarisha-13 followed by BARI Sarisha-15 (5.24 cm), Improved Tori-7 (4.94 cm) and SAU SR-3 (4.83 cm) whereas the minimum silica length was found in BARI Sarisha-16 (4.42 cm) that was similar to SAU SR-3 and Improved Tori-7. This result was in conformity to the finding of Akhter (2005) who pointed out that variations in silica length among the varieties were statistically significant. Hossain et al. (1996) also reported that the varieties differed significantly in respect of silica length. It has been also reported that the napus group showed higher silica length than that of juncea group (BARI, 2001).

Interaction effect of planting technique and variety
The maximum silica (7.41 cm) was obtained from conventional planting technique with the variety BARI Sarisha-13 (P₁V₂), which was statistically similar with the same variety sown in puddle soil (P₂V₂), and the smallest silica (4.29 cm) from BARI Sarisha-16 in puddle soil (P₂V₄) which was statistically similar with P₁V₄ (4.55 cm), P₁V₅ (4.85 cm), P₂V₃ (4.91 cm) and P₂V₅ (4.82 cm) (Fig. 1).

Fig. 1. Interaction effect of planting technique and variety on silica length of rapeseed and mustard

P₁ = Conventional technique, P₂ = Puddle soil, V₁ = Improved Tori-7, V₂ = BARI Sarisha-13, V₃ = BARI Sarisha-15, V₄ = BARI Sarisha-16, V₅ = SAU SR-3

Number of silica plant⁻¹

Effect of planting technique
There was no significant variation of silica number plant⁻¹ observed between the two planting technique though the numerically higher number of silica plant⁻¹ (118.11) was found in the conventional planting method and lower number of silica plant⁻¹ (109.53) was obtained from the puddle soil condition (Table 1).
Effect of variety
The highest number of siliqua plant\(^1\) (143.67) was observed in \(V_4\) which was statistically similar with \(V_5\) (134.15) and \(V_1\) (116.90) while the lowest number of siliqua (83.95) was obtained from \(V_3\) which was statistically similar with \(V_2\) (90.43). Akhter (2005), Roy (2008) and Mamun et al. (2014) agreed with the result of this finding that the number of siliqua plant\(^1\) of rapeseed mustard was significantly affected by the varieties.

Interaction effect of planting technique and variety
The maximum number of siliqua plant\(^1\) (145.20) was obtained from conventional planting technique of the variety BARI Sarisha-16 (\(P_1V_4\)), which was statistically similar with the same variety sown in puddle soil (\(P_2V_4\)), \(P_1V_5\) (138.67), \(P_1V_1\) (131.20) and \(P_2V_5\) (129.63). The lowest number of siliqua plant\(^1\) (80.43) was obtained from BARI Sarisha-15 in puddle soil (\(P_2V_3\)) which was statistically similar with \(P_1V_2\) (88.00), \(P_1V_3\) (87.47), \(P_2V_2\) (92.87) and \(P_2V_1\) (102.60) (Fig. 2).

Number of seeds siliqua\(^1\)

Effect of planting technique
There was no significant variation of number of seeds siliqua\(^1\) observed between the two planting technique though the numerically higher number of seeds siliqua\(^1\) (18.34) was found in the puddle soil condition and lower number of siliquae siliqua\(^1\) (17.99) was obtained from the conventional planting method (Table 1).

Effect of variety
The highest number of seeds siliqua\(^1\) (22.34) was observed in BARI Sarisha-15 (Table 1) which was statistically similar with BARI Sarisha-13 (21.32) and the lowest number of seeds siliqua\(^1\) (12.95) from BARI Sarisha-16 which was statistically similar with Improved Tori-7 variety(15.55).Variation in seeds siliqua\(^1\) among the varieties was in conformity with Mamun et al. (2014), who found the highest seeds siliqua\(^1\) in BARI Sarisha-13 and the lowest seeds siliqua-1 in BARI Sarisha-16 This result supports the findings of Jahan and Zakaria (1997) and Gurjar and Chauhan (1997). Variation in seeds siliqua\(^1\) among the varieties was also in conformity with Islam et al. (1994) who found a significant variation in number of seeds siliqua\(^1\) among different varieties of mustard and rapeseed.
Performance of Rapeseed and Mustard

Interaction effect of planting technique and variety on siliqua number/plant of rapeseed and mustard

The maximum number of seeds siliqua\(^1\) (23.32) was obtained from conventional planting technique of the variety BARI Sarisha-15 (P\(_1\)V\(_3\)), which was statistically similar (22.75) with BARI Sarisha-13 (P\(_2\)V\(_2\)), BARI Sarisha-15 (P\(_2\)V\(_3\)), BARI Sarisha-16 (P\(_1\)V\(_2\)), and SAU SR-3 (P\(_1\)V\(_5\)). The lowest number of seeds siliqua\(^1\) (12.30) was obtained from BARI Sarisha-16 in puddle soil (P\(_2\)V\(_4\)) which was statistically similar with P\(_1\)V\(_4\) (13.60), P\(_2\)V\(_1\) (15.91) and P\(_1\)V\(_1\) (15.20) (Fig. 3).

Weight of 1000 - seeds

Effect of planting technique

There was no significant variation of 1000-seed weight observed between the two planting technique though numerically higher weight (3.79 g) was found in the conventional planting method and lower weight (3.45 g) from the puddle soil.

Biswas et al. condition (Table 2). This result was in conformity with the findings of Hossain et al. (2013) who reported that 1000-seed weight did not show any significant variation due to sowing method (Table 2).

**Effect of variety**

The maximum weight of 1000-seeds (4.07 g) was observed in BARI Sarisha-13 followed by BARI Sarisha-16 (Table 2) which was followed by SAU SR-3 (3.69 g) and Improved Tori-7 (3.07 g) and the lowest 1000-seed weight (3.21 g) from BARI Sarisha-15. Mamun et al. (2014) also observed that BARI Sarisha-13 had the highest 1000-seed weight (4.00 g) whereas the lowest (2.82 g) in SAU Sarisha-3.

P₁ = Conventional technique, P₂ = Puddle soil, V₁ = Improved Tori-7, V₂ = BARI Sarisha-13, V₃ = BARI Sarisha-15, V₄ = BARI Sarisha-16, V₅ = SAU SR-3

**Interaction effect of planting technique and variety**

The maximum 1000-seed weight (4.35 g) was obtained from conventional planting technique of the variety BARI Sarisha-16 (P₁V₄), which was statistically similar (4.09 g) with BARI Sarisha-13 sown in conventional method (P₁V₂) and puddle soil condition, P₂V₂ (4.05 g). The lowest1000-seed weight (2.87 g) was obtained from Improved Tori-7 in puddle soil (P₂V₁) which was statistically similar with P₂V₃ (3.04 g) (Fig. 4).
Performance of Rapeseed and Mustard

Fig. 4. Interaction effect of planting technique and variety on 1000-seed weight of rapeseed and mustard

P₁ = Conventional technique, P₂ = Puddle soil, V₁ = Improved Tori-7, V₂ = BARI Sarisha-13, V₃ = BARI Sarisha-15, V₄ = BARI Sarisha-16, V₅ = SAU SR-3

Seed yield

Effect of planting technique

There was no significant variation of seed yield observed between the two planting techniques though the numerically higher seed yield (1.89 t ha⁻¹) was found in the conventional planting method and the lower seed yield (1.56 t ha⁻¹) from the puddle soil condition (Table 2). This result was at par with the findings of Sarkees (2013) who did not show any variation of mustard seed yield due to planting techniques.

Effect of variety

Higher seed yield (2.24 t ha⁻¹) was observed in Improved Tori-7 variety (Table 2) which was followed by BARI Sarisha-16 (1.96 t ha⁻¹) and BARI Sarisha-13 (1.57 t ha⁻¹). The lowest seed yield (1.34 t ha⁻¹) was obtained from V₃ (BARI Sarisha-15) which was statistically similar with SAU SR-3 (1.53 t ha⁻¹). The result agreed with Rahman (2002), BARI (2001), Zaman et al. (1991) and Mendham et al. (1981) who reported that seed yield of rape and mustard were varied with different varieties.

Interaction effect of planting technique and variety

The highest seed yield (2.39 t ha⁻¹) was obtained from conventional planting technique of the variety BARI Sarisha-16 (P₁V₄), which was statistically similar with the variety Improved Tori-7 sown in puddle soil (P₂V₁) and same variety in conventional planting method of P₁V₁ (2.11 t ha⁻¹). The lowest seed yield (1.11 t ha⁻¹) was obtained from BARI Sarisha-15 in puddle soil (P₂V₃) which was statistically similar with P₂V₅ (1.38 t ha⁻¹) (Fig. 5).

Figure 5. Interaction effect of planting technique and variety on seed yield of rapeseed and mustard

P₁ = Conventional technique, P₂ = Puddle soil, V₁ = Improved Tori-7, V₂ = BARI Sarisha-13, V₃ = BARI Sarisha-15, V₄ = BARI Sarisha-16, V₅ = SAU SR-3

Conclusion
Biswa et al.
The planting method did not show any significant variations in all the studied parameters except siliqua length. Variety showed significant influence on all the studied parameters. The highest seed yield (2.39 t/ha) was obtained from conventional planting technique of the variety BARI Sarisha-16 and the lowest seed yield (1.11 t/ha) was obtained from BARI Sarisha-15 in puddle soil. Based on the results of the study, it could be concluded that rapeseed and mustard can be cultivated in puddle soil without any yield loss. Mustard var. BARI Sarisha-16 in conventional method and Improved Tori – 7 in both conventional and puddle soil condition showed higher yield performance compared to that of other varieties.
