Abstract:
Background: Diabetes mellitus is one of the important risk factors for coronary artery disease. The hemoglobin A1c is used for evaluating glycemic control in diabetic patients. Here, we conducted the study to evaluate the relationship between HbA1c level and severity of coronary artery disease among the hospitalized patients with ACS.

Materials & Methods: This cross sectional study was conducted in the department of Cardiology, Ibrahim Cardiac Hospital & Research Institute, Dhaka, Bangladesh from September 2015 to December 2015. Total of one hundred patients were studied and they were grouped on the basis of their glycaemic status. One hundred patients with acute coronary syndrome were enrolled in this study. Out of them fifty were diabetic (HbA1c>6.5%) and rest of were nondiabetics (HbA1c<6.5%) (group-A and B).

Results: Out of one hundred patients fifty eight were male and forty two were female. Mean age of patients in group-A was 58.54±10.22 years and mean age of patients in group-B was 54.52±13.69 years. Mean age of male and female was 57.72±11.48 years and 54.0±13.08 years respectively. Mean HbA1c of patients in group-A was 11.43±1.43% and group-B was 6.34±0.915%. 38% of group-A and 22% of group-B had triple vessel disease, 26% of group-A and 20% of group-B had double vessel disease and 28% of group-A and 18% of group-B had single vessel disease, and 8% of group-A and 40% of group-B had normal coronary arteries. 48% patients of age group 46-50 in group-A had more incidence in coronary artery disease than other age group which was statistically significant (p=0.035). 61-75 years age group in group-B patients had coronary artery disease than other age groups which was statistically not significant (p=0.084). Patients of group-A was significantly relation with coronary artery disease (p>.001) and six times greater coronary artery disease than patients of group-B (OR= 6.15, 95% CI for OR =2.074 -18.289).

Conclusions: In this way the importance of appropriate glycaemic control has been emphasized in diabetic patients. This study showed the relation between HbA1c levels and the severity of CAD in patient with type-II diabetes mellitus. Our findings demonstrate that elevated HbA1c level was risk factor for severity of coronary artery disease in ACS patients.

Keywords: HbA1c; Coronary artery disease; Acute coronary syndrome.
Introduction:
Chronic hyperglycemia in type 2 diabetes increases the risk of macrovascular events. Though there is continuing uncertainty about its effect on macrovascular outcomes and death, several studies have clearly demonstrated a correlation between type 2 diabetes and acute coronary syndromes (ACS). High prevalence of diabetes and undiagnosed diabetes or pre-diabetic states is seen in patients with stable or unstable coronary artery disease (CAD). This link can be attributed to hyperglycemia, insulin resistance, and a clustering of the risk factors for atherosclerosis. Potential mechanisms that could explain the relationship between diabetes mellitus and ACS including decreased insulin sensitivity leading to impaired glucose oxidation, increased levels of catecholamines leading to increased myocardial damage and infarct size, hyperglycemia-induced osmotic diuresis and volume depletion, enhanced platelet activation, and inflammatory-immune reactions with increased markers of inflammation. Fatty acids-mediated inhibition of glucose oxidation leads to myocardial cell death, injury of cardiomyocyte plasma membrane, calcium overload, and arrhythmias. Several studies have shown prognostic role of hyperglycemia and diabetes in patients with ACS. Hyperglycemia at admission for ACS is associated with less favorable outcome.

Though acute hyperglycemia may be due to the preexisting diabetes mellitus, it may also occur as a part of stress response to the disease state. Hemoglobin A1c (HbA1c) is a stable indicator of unstressed long-term glycemic control and may provide insight into the relation between chronic glucose control and patient outcomes. Thus HbA1c level being a stable indicator of unstressed long-term glycemic control may be a more useful predictor in ACS. HbA1c level is an indicator of average blood glucose concentrations over the preceding 2-3 months, which is a convenient and well known biomarker in clinical practice. It is now recommended as the preferred method for diagnosis and monitoring glycemic control in diabetes mellitus. Studies evaluating the association of HbA1c with ACS have reported discrepant results. Several studies showed higher crude mortality rate in patients with elevated HbA1c following adjustment for many cardiovascular risk factors.

Patients with elevated HbA1c but without known diabetes likely have diabetes that was neither diagnosed nor treated and other relevant cardiovascular risk factors such as hypertension and dyslipidemia that were also untreated before hospitalization, whereas those with diabetes are more likely to be treated with insulin and control the established risk factors. Thus, the prognostic value of HbA1c level in patients with coronary atherosclerotic disease has not been well characterized and remains controversial. This study was an attempt to know the association between HbA1c and severity of coronary disease in ACS patients.

Materials and Methods:
This cross sectional study was done in the department of cardiology, Ibrahim Cardiac Hospital & Research Institute, Dhaka, Bangladesh from September, 2015 to December, 2015. A total of 100 cases admitted in CCU with complaints of typical chest pain and diagnosed as ACS and divided into diabetic (HbA1c > 6.5%) and non-diabetic group (HbA1c < 6.5%) (group A and group B). Patients belonging to age group of 28-85 years, with diagnosis of diabetes mellitus as per American Diabetes Association (ADA) criteria on treatment were selected. Patients with multi-organ failure, congenital or rheumatic heart disease or recent surgery were excluded from the study. Acute coronary syndrome encompasses a) ST-Segment Elevation Myocardial Infarction (STEMI), a condition for which immediate reperfusion therapy should be considered, b) Non-ST-Segment Elevation Myocardial Infarction (NSTEMI) and c) Unstable angina.

After screening, details of patients with regard to symptoms, duration of diabetes mellitus, medical history, and history of smoking were collected. All patients underwent thorough physical examination and the biochemical investigation. They included HbA1c, serum troponin-I, creatinine kinase-MB (CK-MB), electrocardiogram (ECG), and echocardiography. Symptoms of ACS included chest pain, shortness of breath, nausea, vomiting, palpitations, sweating, and anxiety. ACS was established on at least two of the following characteristic symptoms, electrocardiographic changes, typical rise and fall in biochemical parameter like troponin-I was measured.

Statistical analysis: Mean ± standard deviation was reported for continuous variables, and percentages (number) were reported for categorical variables. Continuous variables were compared using unpaired Student’s t-test, and categorical variables were compared using Chi-square tests. Odds ratios (ORs) and 95% confidence intervals (CIs) were calculated for each independent variable. All comparisons were two-tailed and P < 0.05 was considered statistically significant. The entire analysis was performed with Statistical Package for the Social Sciences (SPSS) version 19.0.

Results:
Out of one hundred patients 58 were male (in group A had 26 and group B had 32) and 42 were female (24 were in group A and 18 were in group B). Mean age of patients in group A was 58.54±10.22 years and group B was 54.52±13.69 years. Mean male age was 57.72±11.48 years and mean female age was 54.02±13.08 years (Table 1). Group A patients mean HbA1c was 11.43±1.43% and group B patients mean HbA1c was 6.34±0.915%.
Table-I

\[ \begin{array}{l|c|c|c|c} \hline \text{Age group (years)} & \text{Group A (n=50)} & \text{Group B (n=50)} & \text{p-value} \\ \hline \text{n} & \% & n & \% \\ \hline 28-45 & 5 & 10 & 16 & 32 \\ 46-60 & 26 & 52 & 17 & 34 \\ 61-75 & 16 & 32 & 15 & 30 \\ 76-85 & 3 & 6 & 2 & 4 \\ \hline \text{Mean ± SD} & 58.54±10.22 & 54.52±13.69 & \text{NS} \\ \hline \end{array} \]

Eighty percent patients of group-A and eighty six percent patients of group-B had hypertension which was statistically not significant (p=0.616). 86% patients of group-A and 52% patients of group-B had dyslipidaemia which was statistically significant (p=.001). 38% patients of group-A and 64% patients of group-B were smoker which was not statistically significant(p=0.148). Positive family history for IHD was statistically significant(p= 0.001)in both group (Table-2).

Table-II

\[ \begin{array}{l|c|c|c|c} \hline \text{Risk factor} & \text{Group A (n=50)} & \text{Group B (n=50)} & \text{p-value} \\ \hline \text{n} & \% & n & \% \\ \hline \text{Smoking Habit} \\ \text{Smoker or Ex-smoker} & 19 & 38 & 17 & 34 & .148^{\text{NS}} \\ \text{Non-smoker} & 31 & 62 & 33 & 66 \\ \hline \text{Hypertension} \\ \text{Yes} & 40 & 80 & 43 & 86 & .616^{\text{NS}} \\ \text{No} & 10 & 20 & 7 & 14 \\ \hline \text{Dyslipidaemia} \\ \text{Yes} & 43 & 86 & 26 & 52 & .001^{\text{S}} \\ \text{No} & 7 & 14 & 24 & 48 \\ \hline \text{Family H/O IHD} \\ \text{Yes} & 29 & 58 & 23 & 46 & .001^{\text{S}} \\ \text{No} & 21 & 42 & 50 & 78.1 \\ \hline \end{array} \]

\text{NS = Not Significant, S = Significant}

Out of one hundred patients, BMI of 53 patients were within 25-29.9. Ten patients BMI range was 30-34.9 and thirty seven patients BMI range was 18.4-24.9.(Fig-1)

Table-III

\[ \begin{array}{l|c|c|c} \hline \text{CAD} & \text{Group-A} & \text{Group-B} & \text{p-value} \\ \hline \text{SVD} & 14 (28\%) & 9 (18\%) & \text{NS} \\ \text{DVD} & 13 (26\%) & 10 (20\%) & 0.776^{\text{NS}} \\ \text{TVD} & 19 (38\%) & 11 (22\%) \\ \text{Normal} & 4 (8\%) & 20 (40\%) & \text{NS} \\ \hline \end{array} \]

\text{NS=Not significant}

Within group-A, 46-60 years age group had more incidence(48%) in coronary artery disease than other age group which was statistically significant ( p=0.035). In group- B, 61-75 years age group had more frequency(26%) of coronary artery disease than other age groups which was statistically not significant(p=0.084). (Table-4)

Table-IV

\[ \begin{array}{l|c|c|c} \hline \text{Age Group} & \text{Group-A} & \text{p-value} & \text{Group-B} & \text{p-value} \\ \hline \text{Years} & \text{Frequency} & \text{Percentage (\%)} & & \text{Frequency} & \text{Percentage (\%)} \\ \hline 28-45 & 3 & 6 & & 7 & 14 \text{0.035}^{\text{S}} \\ 46-60 & 24 & 48 & 0.035^{\text{S}} & 9 & 18 & 0.084^{\text{NS}} \\ 61-75 & 16 & 32 & 13 & 26 \\ 76-85 & 3 & 6 & 1 & 2 \\ \hline \end{array} \]

\text{NS = Not Significant, S = Significant}
Out of 100 patients, 46 patients of group A and 29 patients of group B had coronary artery disease which is statistically significant (p<0.05). Adjusted OR for association of elevated HbA1c with acute coronary syndrome when analyzed by regression analysis adjusting for confounders like dyslipidemia, family history of ischemic heart disease. HbA1c showed strong relation with adjusted odds ratio =6.159 (CI: 2.074-18.289). (Table-V)

Discussion:

Many studies have clearly demonstrated the strong association of HbA1c with macrovascular complications in type II diabetes mellitus. There are few studies in the western literature reporting the association of HbA1c with macrovascular complications like ACS. The present study was done to know the relationship of HbA1c level with ACS in our population. The cohort study done by Selvin and colleagues [14] on 7435 patients with type 2 diabetes mellitus has shown that 1% increase HbA1c was associated with 18% increase in the risk of coronary heart disease.

In our study, difference between mean HbA1c among group-A and group-B was statistically significant. Subgroup analysis based on status of dyslipidaemia and positive family history of IHD also showed similar results. The prospective population study done by Khaw KT et al., [15] on 10232 subjects has shown that after adjustment for systolic blood pressure, cholesterol level, body mass index, waist-hip ratio, smoking, and previous myocardial infarction or stroke, there was a 21% increase in cardiovascular events for every 1% increase in HbA1c level above 5%.

According to age patients were categorized into different age group, group-A & B, within 46-60 years age group of group-A (p = 0.035) had higher frequency of coronary artery disease, on the other hand, 61-75 age group of group-B (p=0.084) had also higher frequency of coronary artery disease which was statistically not significant on the other hand. Higher incidence of coronary artery disease found in Razu HN et al.[11] and Mehmet FO et al.[13]. There are several biologically possible mechanisms that might account for the finding that chronic hyperglycemia is associated with ACS. Hyperglycemic periods play a major role in the activation of oxidative stress and overproduction of mitochondrial superoxide, which trigger various metabolic pathways of glucose-mediated vascular damage[16,17]. Glucose can react with various proteins to form advanced glycation end products, which may contribute to long term complications in diabetes, plaque formation, and atherosclerosis [18]. These effects are gradual and likely to be cumulative, occurring during decades of exposure to chronically elevated blood glucose levels. Elevated HbA1c level is likely the result of long-term insulin resistance.

Metabolic disturbances associated with insulin resistance including hyperglycemia, dyslipidemia, hypercoagulability, and inflammation might play a major role in the adverse impact of elevated HbA1c on cardiovascular system. Limitations of the present study was small group of patients so that we did not collect the long term follow up details and mortality associated with ACS in relation to HbA1c level. The number of patients in each group was also small to calculate cardiovascular risk with increase in percentage of HbA1c.

Conclusion:

HbA1c level was strongly related with risk of coronary artery disease specially those patients who were diagnosed as ACS. Occurrence of ACS was significantly more in patients with diabetic with poorly controlled blood sugar level when compared with nondiabetic patients. Our finding supports the notion that diabetic patients with higher HbA1c level should be closely followed due to their higher risks of cardiovascular outcomes. Glycemic control may help to reduce cardiovascular events in type 2 diabetic patients.
