Abstract

A field experiment was conducted in the research field of Sher-e-Bangla Agricultural University (SAU), Dhaka, Bangladesh to study variability and heritability in *Brassica rapa* L. for developing short durable, high yielding varieties. The experiment had laid out in a randomized complete block design with three replications and consisted of seven genotypes viz., G\(_1\) (BARI Sarisha-14), G\(_2\) (Brown Special), G\(_3\) (Yellow Special), G\(_4\) (Tori-7), G\(_5\) (BARI Sarisha-17), G\(_6\) (BARI Sarisha-15) and G\(_7\) (BARI Sarisha-6). The result revealed that G\(_7\) had the highest yield plant\(^1\) (6.91 g) and longest duration (108 days) while G\(_4\) had the lowest yield plant\(^1\) (4.12 g) and G\(_2\) had the shortest duration (79 days). High genotypic and phenotypic coefficient of variation for number of secondary branches plant\(^-1\) (95.4% and 99.4%), number of siliqua plant\(^-1\) (29.6% and 30.3%), plant height (25.2% and 25.4%) and number of seeds siliqua\(^-1\) (26.76% and 27.2%) had estimated. High heritability with high genetic advance and gain had observed for days to 80% maturity (99.9%, 21% and 23.4%), plant height (98.55%, 53.99% and 51.6%) and number of siliqua plant\(^1\) (95.4%, 101.3% and 59.4%). While high heritability with low genetic advance and high genetic gain were observed for number of primary branches plant\(^1\) (92.1%, 0.70% and 188.4%), number of secondary branches plant\(^1\) (92.02%, 7.47% and 188.43%), length of siliqua (98.3%, 1.104% and 29.96%), 1000 seed weight (84.6%, 1.23% and 32.01%) and yield plant\(^1\) (97.4%, 2.01% and 38.47%). Days to 80% maturity, plant height and number of siliqua plant\(^1\) showed high heritability with high genetic advance and genetic gain indicated additive gene action and selection could be useful for these traits. While high heritability with low genetic advance had observed for number of primary and secondary branches plant\(^1\), length of siliqua, 1000 seed weight and yield plant\(^1\) indicated non additive gene action and selection might be ineffective for these traits.

Keywords: Additive gene, Genetic advance, Genetic gain, Heritability, Variance

Introduction

Mustard and rapeseed have become the major oilseed crops occupying the third position among the oilseed crops in the world and the world area harvested under mustard

\(^*\) Corresponding author: shely.sau302@gmail.com
and rapeseed is 38,509,853 MT, and production is 75,711,806 MT (FAOSTAT, 2020). The climate and soil conditions of Bangladesh is also preferable for mustard and rapeseed production (Chowdhury et al., 2014). In Bangladesh total cultivated area under rapeseed and mustard cultivation is 0.589 million hectares which produces 1.34 ton ha\(^{-1}\) in 2020-21 and \(B.\ rapa\) occupies the 1\(^{st}\) position in respect of area and production (AIS, 2022).

Although short durable, low yielding and pest susceptible variety (Tori-7) of \(B.\ rapa\) is popular in Bangladesh but there is still lack of improved short durable and high yielding varieties. As a result, Bangladesh is suffering from an acute shortage of edible oil and therefore, it is very important to develop new varieties with such desirable traits. Varietal improvement requires a laborious and long term breeding activities, which depends on the extent and nature of genetic variability, heritability, and genetic advance present in the genotypes (Islam et al., 2020 and Snehi et al., 2020). The more the variability in the breeding population the more effective selection will be achieved (Rauf and Rahim, 2018). Genetic variability and heritability had estimated by different morphological parameters that involve polygenic inheritance of gene action (Ali et al., 2013, Azam et al., 2013 and Iqbal et al., 2014). Polygenic inheritance of gene action has higher environmental influences so heritability estimation is very much important to ensure an effective selection process as it shows the influence of genes and environment on different morphological traits (Sultana et al., 2021). Heritability and phenotypic variance along with the selection intensity can give the most accurate estimate of genetic advance for effective selection (Parvin et al., 2020). High heritability along with high genetic advance for a particular trait indicated most effective selection condition (Bibi et al., 2016; Rauf and Rahim, 2018 and Mazurkievicz et al., 2019). For developing a high yielding variety, it is very important to estimate the individual role of different morphological traits on higher yield (Ejaz-Ul-Hasan et al., 2014). Therefore, the present study had conducted to estimate the variability, heritability and genetic advance for yield and yield related attributes in \(B.\ rapa\) (main oil yielding species in Bangladesh) for developing short durable and high yielding genotypes. This would provide a guide for effective selection in the breeding population in formulating the most appropriate breeding technique for improvement of various traits.

Materials and Methods

Study area

The experiment had conducted in the research field of SAU, Dhaka, Bangladesh from October/20 to March/21.

Plant materials

The plant materials of the present study consisted of seven genotypes of \(B.\ rapa\) collected from Bangladesh Agricultural Research Institute (BARI) and Department of Genetics and Plant Breeding, Sher-e-Bangla Agricultural University, Dhaka, Bangladesh, which included \(G_1\) (BARI Sarisha-14), \(G_2\) (Brown Special), \(G_3\) (Yellow Special), \(G_4\) (Tori-7), \(G_5\) (BARI Sarisha-17), \(G_6\) (BARI Sarisha-15) and \(G_7\) (BARI Sarisha-6).
Materials and Methods

The experiment had laid out in a randomized complete block design (RCBD) with three replications. The genotypes had randomly distributed to each replication having row spacing of 30 cm and plant distance of 10 cm. Three rows of each accession had sown in each replication. Ten plants had selected at random from each replication and data on ten quantitative parameters namely; days to 50% flowering, days to 80% maturity, plant height, number of primary branches plant\(^{-1}\), number of secondary branches plant\(^{-1}\), number of siliqua plant\(^{-1}\), siliqua length, number of seeds siliqua\(^{-1}\), 1000 seed weight and seed yield plant\(^{-1}\) had noted.

Statistical analysis

Means separated using Least Significant Difference test. The analysis of variance for different characters had carried out using mean data in order to assess the genetic variability among populations as given by Cochran and Cox (1957). The broad sense heritability (\(h^2_{G}\)) was estimated for all characters as the ratio of genotypic variance to the total of phenotypic variance as suggested by Lush (1949) and Hanson et al. (1956) and had categorized according to Robinson et al. (1966). Genetic advance had measured and categorized using the formula given by Johnson et al. (1955). Genotypic and phenotypic co-efficient of variation had been calculated by the formula of Burton (1952) and had categorized as suggested by Sivasubramanian and Madhamon (1973).

Results and Discussion

Analysis of variance

Analysis of variance was performed for ten quantitative characters including yield and yield-attributing traits for selected \(B. rapa\) genotypes (Table 1) and observed that mean sum of squares due to genotypes were significant for all the studied traits at 1% level of significance, thus exhibiting the presence of considerable genetic variability except primary branches plant\(^{-1}\). Singh et al., (2013), Tripathi et al., (2013) and Shekhawat et al., (2014) also reported considerable genetic variability for all these traits in their experiments, as mean sum of squares due to genotypes were significant. Abideen et al., (2013) also studied non-significant differences in primary branches plant\(^{-1}\) among the genotypes. This might be due to environmental effects.

Mean performance

Significant variation in days to 50% flowering and 80% maturity had observed which ranged from 34.33 to 58.86 days and 79.33 to 108.00 days respectively (Table 2). Days to 50% flowering was maximum in \(G_7\) (58.86 days) and the minimum in \(G_4\) (34.33 days) while days to 80% maturity was maximum in \(G_7\) (108.00 days) and the minimum in \(G_2\) (79.33 days). The result matched with the findings of Karmokar (2018) and Ullah
Variability and heritability study in rapeseed (2018) who reported days to 50% flowering for different lines and varieties of *B. rapa* ranged from 33.00 to 57.33 days and 27.33 to 55.66 days respectively while days to 80% maturity ranged from 78.00 to 89.67 and 78.33 to 87.33 days respectively. Minimum days of 50% flowering indicated short durable population. Plant height ranged from 67.86 to 149.23 cm. The highest plant height was recorded in G7 (149.23 cm) and lowest in G4 (67.86 cm) (Table 2). The result differed from the findings of Karmokar (2018) and Ullah (2018) who reported that, the plant height for different lines and varieties of *B. rapa* ranged from 80.77 to 111.47 cm and 94.56 to 107.73 cm respectively. This might be due to environmental effects. The number of primary and secondary branches plant\(^{-1}\) ranged from 6.53 to 9.13 and 0.13 to 9.80 respectively (Table 2). The maximum primary branches plant\(^{-1}\) had recorded in G6 (9.13) and the minimum was in G5 (6.53) while the secondary branches plant\(^{-1}\) had found to be the maximum in G4 (9.80) and the minimum was in G6 (0.13). The more branches plant\(^{-1}\) indicating more siliqua that ultimately increased yield plant\(^{-1}\). The result had supported by Karmokar (2018) who reported that number of primary and ranged from 59.48 to 124.29, 96.54 to 124.44 and 78.00 to 180.3 respectively. Number of seeds siliqua\(^{-1}\) ranged from 11.85 to 30.97 (Table 2). It was maximum in G5 (30.97) followed by G6 (24.11) which was statistically similar with G1 (23.99) while the minimum number was in G4 (11.85). Ali *et al.*, (2002) observed that the hybrid of *B. rapa* produced an excellent number of seeds siliqua\(^{-1}\) (25.06) while Karmokar (2018) and Ullah (2018) found that the seeds siliqua\(^{-1}\) for different lines and varieties of *B. rapa* ranged from 5.13 to 10.33 and 0.50 to 10.93 respectively but higher than the findings of Ullah (2018) who estimated that the range was between 5.67 to 4.12 and 1.45 to 2.27 respectively. The result of the present study exceeded the range of this finding. Which might be due to the differences in size and shape of siliqua in different genotypes. The siliqua length ranged from 3.04 to 4.57 cm. The highest siliqua length had measured in G2 (4.57 cm) followed by G7 (4.14 cm) while the lowest in G4 (3.04 cm) preceded by G1 (3.18 cm) and G3 (3.36 cm) (Table 2). secondary branches plant\(^{-1}\) for different lines and varieties of *B. rapa* ranged from 5.13 to 10.33 and 0.50 to 10.93 respectively but higher than the findings of Ullah (2018) who estimated that the range was between 5.67 to 4.12 and 1.45 to 2.27 respectively. This might be due to environmental effects. Number of siliqua plant\(^{-1}\) ranged from 90.64 to 246.53 (Table 2). It was maximum in G4 (246.53) followed by G2 (219.66) while the minimum number was in G1 (90.64). The findings exceeded the range reported by Naznin *et al.*, (2015), Karmokar (2018) and Ullah (2018) who reported that the number of siliqua plant\(^{-1}\) for different lines and varieties of *B. rapa*.

Similar result had been observed by Karmokar (2018) and Ullah (2018) who reported that silquia length for different lines and varieties of *B. rapa* ranged from 4.67 to
5.96 cm and 5.07 to 6.38 cm respectively. 1000 seed weight ranged from 2.86 to 4.75. The highest 1000 seed weight had recorded in G7 (4.75 g) and the lowest in G4 (2.86 g) while significant variation for seed yield plant⁻¹ was observed among the genotypes and it ranged from 4.12 to 6.91 g (Table 2). The highest yield was recorded in G7 (6.91 g) followed by G5 (6.09 g) and the lowest yield was recorded in G4 (4.12 g) preceded by G1 (4.93 g). The higher 1000 seed weight indicated that the seeds are bigger and contained higher amount of oil. These result matched with the findings of Karmokar (2018) and Ullah (2018) who reported that 1000 seed weight for different lines and varieties of B. rapa ranged from 3.33 to 4.53 g and 2.50 to 3.63 g respectively and for seed yield plant⁻¹ it ranged from 3.53 to 7.31 g and 5.65 to 7.48 g respectively.

**Variability**

For days to 50% flowering and days to 80% maturity phenotypic variance (78.42 and 104.02 respectively) were higher than the genotypic variance (78.34 and 103.94 respectively). High values of phenotypic coefficient of variation (PCV) (20.12 %) and genotypic coefficient of variation (GCV) (20.11 %) had observed for days to 50 % flowering while 80 % maturity exhibited moderate GCV and PCV of 11.34 and 11.35 % respectively (Table 3). The difference between genotypic and phenotypic variances and PVC and GVC were relatively low for these traits. Hussain et al., (2014) and Rout et al., (2019) also found similar result that indicated the less influence of environment on the expression of the characters. The high value for PVC and GVC had estimated here but Sikarwar et al., 2017; found low PCV and GCV that may be due to environmental factors. For plant height, Genotypic and phenotypic variance were 697.14 and 707.37 respectively with large environmental influence (10.23). The PCV and GCV also had the higher values, 25.38 and 25.19 % respectively (Table 3). Iqbal et al., (2015), Naznin et al., (2015) and Aktar et al., (2019) also found the similar results. High PCV and GCV values for this traits had supported by Gupta et al., (2019), indicated the existence of inherent variability among the studied genotypes for this trait. The genotypic and phenotypic variance were recorded as 0.40 and 1.43 respectively along with low GCV (8.64 %) and moderate PCV (16.18 %) for of primary branches plant⁻¹ while for secondary branches plant⁻¹, the genotypic and phenotypic variance were recorded as 14.30 and 15.53 respectively along with very high GCV (95.35 %) and PCV (99.39 %) (Table 3). Relatively low differences between genotypic and phenotypic variance for number of primary branches plant⁻¹ indicated less environmental influences, this result matched with Hussain et al., 2014; and Naznin et al., 2015; Iqbal et al., 2015; and Rout et al., 2019; also estimated low GCV and moderate PCV but Sikarwar et al., 2017; and Gupta et al., 2019; reported high GCV and PCV for this trait. For number of silhquia plant⁻¹, phenotypic variance (2658.44) was higher than genotypic variance (2534.23) (Table 3).

High genotypic variance indicates the better transmissibility of the character from parent to their offspring. Higher value of PCV (30.23%) and GCV (29.52%) had also estimated for this trait indicated the existence of inherent variability among the studied genotypes but differences between phenotypic and genotypic variance was relatively higher (124.21) indicated influence of environment (Table 3). The result matched with Aktar et al., (2019), Gupta et al., (2019) and Rout et al., (2019). The genotypic variance (34.42), phenotypic variance (33.52), environmental variance (0.90), high GCV (26.76) and high PCV (27.12) had estimated for number of seeds siliqua$^1$ (Table 3). Very low environmental influences and high GCV, PCV indicated presence of additive gene effects and hence the selection might be effective for this trait. Sikarwar et al., (2017), Aktar et al., (2019) and Rout et al., (2019) also estimated similar result for this trait. The genotypic and phenotypic variance for siliqua length was 0.297 and 0.292 respectively with environmental variance 0.005 (Table 3). Very low difference between genotypic and phenotypic variance indicated very low environmental influences and the preponderance of additive gene effects, hence, the selection, based on these traits might be effective. Naznin et al., (2015) and Rout et al., (2019) also found least difference between phenotypic and genotypic variances for this trait. Moderate GCV (14.67%) and PCV (14.80 %) values were estimated for this trait (Table 3). Salam et al., (2017) also reported moderate GCV and PCV values for this trait. Very low genotypic, phenotypic and environmental variance (0.42, 0.50 and 0.08 respectively), moderate GCV and PVC (16.89 % and 18.36 % respectively) had observed for 1000 seed weight (Table 3). Yield
plant$^1$ also exhibited low genotypic, phenotypic and environmental variance (1.00, 0.98 and 0.02 respectively) with moderate estimates of PCV (19.17%), low GCV (18.92%) (Table 3). Low environmental influences focused on additive gene effects. Aktar et al. (2019) and Rout et al., 2019; also reported less environmental influences for these traits.

**Heritability and genetic advance**

Days to 50% flowering and 80% maturity showed high heritability (99.89 % and 99.92 % respectively) with high genetic advance (20.22 % and 20.99 % respectively) and high genetic gain (41.40 % and 23.36 % respectively) (Fig. 1). High heritability and high genetic advance and gain indicating that this trait was under additive gene control and selection for genetic improvement for these traits would be effective. Sikarwar et al., (2017), Salam et al., (2017), Singh et al., (2018), Aktar et al., (2019) and Gupta et al., (2019) also observed similar result. High heritability (98.55%) coupled with high genetic advance (53.99 %) and genetic gain (51.53 %) had estimated for this trait (Fig. 1). High heritability coupled with high genetic advance and high genetic gain implied that this trait had governed by additive gene action and selection might be effective for further genetic improvement of this trait. Similar result had observed by Bibi et al., (2016), Salam et al., (2017), Singh et al., (2018) and Gupta et al., (2019) for plant height. Low heritability 28.49 % with low genetic advance (0.70%) and low genetic gain 9.50% had estimated for number of primary branches plant$^{-1}$ that indicated non-additive gene effects and selection might be ineffective for this trait. The result agreed with Mekonnen et al., (2014) but did not matched with Naznin et al., (2015), Sikarwar et al., (2017) and Rout et al., (2019) who studied high heritability with high genetic advance for number of primary branches plant$^{-1}$. While for number of secondary branches plant$^{-1}$, high heritability 92.02 % with low genetic advance (7.47%) and very high genetic gain 188.43% were estimated (Fig.1).

Variability and heritability study in rapeseed

Significant variations were observed among the genotypes for all the studied traits. All the characters except plant height, number of siliqua plant\(^1\) showed least difference between genotypic and phenotypic variances, which indicated low environmental influence on those characters. Hence, selection will be beneficial for those traits. The high genotypic and phenotypic coefficient of variation were observed for number of secondary branches plant\(^1\), number of siliqua plant\(^1\), plant height and number of seeds siliqua\(^1\) indicated these characters could be improved by phenotypic selection. High heritability coupled with high genetic advance and genetic gain had observed for days to 80% maturity, plant height and number of siliqua plant\(^1\) indicated selection for these traits could be useful for future breeding program due to prevalence of additive gene action. While high heritability coupled with low genetic advance and high genetic gain were observed for number of primary branches plant\(^1\), number of secondary
branches plant\(^1\), length of siliqua, 1000 seed weight and seed yield plant\(^1\) indicated that, high heritability occurs due to environmental effects, so, selection for genetic improvement of these traits would be ineffective. However, high heritability coupled with moderate genetic advance and high genetic gain were estimated for days to 50% flowering and number of seeds siliqua\(^1\) indicated medium possibility of selection.

**Acknowledgment**

We are grateful to the Department of Genetics and Plant Breeding of Sher-e-Bangla Agricultural University for all sorts of support during conducting the experiment as well as the Ministry of Science and Technology for providing financial support.
