SEPTICAEMIC MELIOIDOSIS COMPLICATED BY SEPTIC ARTHRITIS IN A BANGLADESHI MALE: A CASE REPORT

HASNA FAHMIMA HAQUE1, SUCHISMITA DEBNATH2, SAMIRA RAHAT AFROZE3, FARHANA AFROZ3, MUHAMMAD ABDUR RAHIM4, AKM MUSA5

Abstract
Melioidosis is an uncommon disease in Bangladesh but in recent years increasing numbers of cases are being diagnosed. A case of septicaemic melioidosis occurring in a young Bangladeshi returning worker is reported here. The patient presented with fever and features of septic arthritis. Diagnostic work-up revealed the growth of Burkholderia pseudomallei from blood and synovial fluid cultures. This case highlights the importance of high index of clinical suspicion for melioidosis in appropriate clinical scenario.

Key words: Bangladesh, Burkholderia pseudomallei, fever, melioidosis, septic arthritis.

Introduction
Melioidosis is an infectious disease caused by infection with *Burkholderia pseudomallei*, a Gram-negative bacterium found in soil and surface water. Patients with diabetes mellitus are at increased risk for infection by *B. pseudomallei*. Patients may present with fever, pneumonia, cutaneous and organ abscesses, septic arthritis, genito-urinary infections, etc. Melioidosis is an uncommon diagnosis in Bangladesh though nearly 17,000 cases are estimated to occur annually. Here, we report a case of melioidosis occurring in a diabetic patient who presented with fever and septic arthritis.

Case Report
A 36-year-old Bangladeshi man presented with two and half months history of high grade continued fever along with pain and swelling involving the right shoulder and bilateral knee joints. He returned to Bangladesh two months ago from Malaysia, where he had been involved in farming for few years. His symptoms started while staying in Malaysia and because of worsening symptoms he came back home. For his problems, he initially consulted at Gopalgonj, his local district in Bangladesh and two weeks previously he received an intra-articular steroid injection in right shoulder joint resulting in no benefit. His fever and joint symptoms continued to worsen and he developed vomiting, several episodes a day, for few days before admission under our care. His medical history included diabetes mellitus for which he had been taking metformin.

On admission, the patient was looking very ill, he was febrile with a temperature of 102°F, mildly icteric, tachycardic (pulse 110/min) but had normal blood pressure (125/70 mm Hg). His right shoulder joint (Figure 1) and knee joints (Figure 2) were swollen, hot and tender. He had 2-cm splenomegaly below the
significant sero-epidemiological survey reports organism, Melioidosis is endemic in south-east Asia and northern Australia, but imported cases have been reported elsewhere.\(^2\) Isolation of the causative organism, \textit{B. pseudomallei}, from soil specimen\(^3\), significant sero-epidemiological survey reports\(^3,4\) and autochthonous cases\(^1,5,6\) had confirmed Bangladesh as endemic for melioidosis. Common presentations of melioidosis include fever, pneumonia, abscesses, septic arthritis and genitourinary infections.\(^5,6\) Clinical presentation of melioidosis often mimics tuberculosis and in tuberculosis endemic countries like Bangladesh, it is not unlikely that cases are started with empiric anti-tuberculosis therapy.\(^6,7\) Septic arthritis is common and generally complicates septicemic melioidosis.\(^8,9\) Patients may develop metastatic abscess even while on antibiotic treatment.

Diabetes mellitus is an established risk factor for melioidosis and occasionally an infective episode by \textit{B. pseudomallei} may unmask undetected diabetes.\(^5,6\) Other risk factors include alcoholism, steroid intake\(^5\), renal failure, chronic liver disease, thalassaemia, chemotherapy etc.\(^1\) Our patient had diabetes and hepatitis B virus associated chronic liver disease. Occupational risk factors for melioidosis include farming specially working in wet paddy fields and recreational exposures to soil and waters. The bacterium enters through an abraded skin or by inhalation.\(^5\)

Like any other infectious diseases, culture remains the gold standard for diagnosis of melioidosis. \textit{B. pseudomallei} readily grows in ordinary media from representative samples like blood, urine and pus. Important is to have a high index of clinical suspicion and a good liaison between the treating physician and the microbiologists.\(^1,5\) Growth of \textit{Pseudomonas}-like organisms which are resistant to aminoglycosides and polymyxin/colistin and sensitive to co-amoxiclav is important clue for laboratory personnel and microbiological diagnosis.\(^5\)

Treatment of melioidosis consists of initial intensive therapy with ceftazidime or carbapenems for several weeks followed by eradication phase with oral antibiotics for months often in combinations.\(^5\) Duration of antibiotic treatment depends on severity of disease and sites of involvement. Joint and bone diseases require prolonged treatment and often merits drainage.\(^8\)

Question may arise, whether the index patient acquired melioidosis from Malaysia or in Bangladesh? Such issue has recently been asked by researchers\(^10\) and the answer is not straight forward. But, as the symptoms of our patient started while in Malaysia, he might have acquired infection in Malaysia. Molecular techniques may answer the question.

**Discussion**

Melioidosis is endemic in south-east Asia and northern Australia, but imported cases have been reported elsewhere.\(^2\) Isolation of the causative organism, \textit{B. pseudomallei}, from soil specimen\(^3\), significant sero-epidemiological survey reports\(^3,4\) and autochthonous cases\(^1,5,6\) had confirmed Bangladesh as endemic for melioidosis.

Common presentations of melioidosis include fever, pneumonia, abscesses, septic arthritis and genitourinary infections.\(^5,6\) Clinical presentation of melioidosis often mimics tuberculosis and in tuberculosis endemic countries like Bangladesh, it is not unlikely that cases are started with empiric anti-tuberculosis therapy.\(^6,7\) Septic arthritis is common and generally complicates septicemic melioidosis.\(^8,9\) Patients may develop metastatic abscess even while on antibiotic treatment.
