Abstract

Puerperal sepsis is an important cause of maternal morbidity and mortality in developing countries. This study was undertaken to isolate and identify the Aerobic bacterial agents of Puerperal sepsis among the patients admitted in Mymensingh Medical College Hospital during the period from July, 2006 to June, 2007. Endocervical swabs/secretions were collected from 50 cases of Puerperal sepsis and were cultured aerobically. Out of 50 samples, 42 (84%) yielded growth in cultures. Among 42 culture positive cases, 20 (40%) were Aerobic organisms and 22 (44%) were mixed, i.e., Aerobic and Anaerobic bacteria. The isolated Aerobic organisms were Staphylococcus aureus (26, 61.90%), Escherichia coli (6, 14.28%), Staphylococcus epidermidis (5, 11.90%), Streptococcus pyogenes (3, 7.14%) and Enterococcus faecalis (2, 4.76%). The organisms were identified by standard biochemical tests. All isolates of S. aureus and S. epidermidis were sensitive to Cephalaxin and Vancomycin. Similarly all the strains of E. coli were sensitive to Gentamicin, Amikacin, Ciprofloxacin and Cephalexin. All the strains of S. pyogenes were sensitive to Amoxicillin and all the isolates of Enterococcus were sensitive to Amoxicillin and Cephalexin.

Key words: Puerperal sepsis, Aerobic organisms, Anaerobic organisms, Maternal morbidity and mortality

Introduction

Puerperal sepsis is an infection of the genital tract at the time interval between rupture of amniotic membrane and the 42nd day following delivery or abortion. Two or more of the following manifestations must be present to define the condition. The manifestations are: pelvic pain, fever of 38.45°C or more, abnormal vaginal discharge with foul odour and delayed reduction of uterine size. The recorded incidence of maternal sepsis was 1.7, 0.22, 0.07, 0.15 and 4.5 per 100 live births in Nigeria, Niger, South Africa, USA and Bangladesh respectively.2,4 One study from Nigeria and another from Senegal reported rate of post-partum genital sepsis as 14.8% and 8.7% among women who delivered at home compared to 7.9% and 1.9% in those who delivered in hospitals with proper healthcare facilities respectively.5,6 Over 3.5 million women in Bangladesh become pregnant every year and not less than 20,000 of them die while giving birth to their babies. In Mymensingh Medical College Hospital (MMCH) during the year 1984-88, it was found that 17% maternal death had been caused by Puerperal sepsis.7 Another study in Dhaka Medical College showed 20.3% maternal death due to Puerperal sepsis.8 One of the predisposing conditions usually leading to the Puerperal sepsis is the home delivery in unhygienic conditions and should be included at the top of the list. Other factors include low socioeconomic condition, anaemia, parity as primigravida, prolonged period

of delivery after rupture of the amniotic membrane, frequent per vaginal examinations and prolonged labour.9

The causative organisms of Puerperal sepsis are Streptococcus pyogenes and other Beta-haemolytic Streptococci, Enterococcus faecalis, Anaerobic cocci, Clostridium perfringens, Bacteroides species, Proteus species, Escherichia coli with other Coliforms and Listeria monocytogenes.10 In 1879, Louis Pasteur identified the Streptococcus as the causative organism for Puerperal sepsis. Since the early 1930s, when Rebecca Lancefield reported her grouping system for Haemolytic Streptococci, Group A Streptococcus was widely acknowledged as the major pathogen associated with Puerperal sepsis. Group B Streptococcus (GBS) was initially thought to be a commensal until 1937, while Shet et al in India reported 7 cases of GBS associated Puerperal fever with 3 deaths.11 Staphylococci or faecal Aerobic Gram negative bacteria (5%) were isolated from vaginal swabs.12

Though Puerperal sepsis is the common cause of maternal morbidity and mortality, it appears to be largely preventable with good antenatal check-up, aseptic delivery practices and postpartum care. When care is delayed or inadequate, infection can progress quickly to generalized sepsis, which can result in infertility, chronic disability and even death.2 No study particularly on bacterial aetiology of Puerperal sepsis has been reported. It is known that bacterial pattern with their antimicrobial susceptibility is a dynamic and changing phenomenon and surveillance of this event is needed in every healthcare setting. The study was aimed to determine causative organisms and antibiotic susceptibility of the isolates.

Methods
This was a cross-sectional study carried out in the Department of Microbiology, Mymensingh Medical College for a period of one year from July, 2006 to June, 2007. Clinically diagnosed 50 patients of Puerperal sepsis admitted in different wards of Obstetrics and Gynecology department of Mymensingh Medical College Hospital were selected for this study.

Cases of Puerperal sepsis were selected on basis of the following clinical findings: fever of ≥38.5°C within 6 weeks following termination of pregnancy, pelvic pain with offensive and/or purulent vaginal discharge, abdominal pain, and tender uterus, subinvolution of the uterus, and shock.13 Patients having two or more of the above features were considered as Puerperal sepsis for the present study. Specimens were collected carefully to avoid normal resident flora. A sterile bi-valve Cusco's vaginal speculum was used to visualize the endocervix under sufficient light. Swab/secretion was taken by gentle rubbing of the mucosa of Cervix or Vagina by sterile cotton swab and secretion was taken by aspiration with a sterile disposable syringe. Cervical swab/secretion was inoculated into Blood agar, MacConkey's agar, Nutrient agar and Mannitol salt agar media and incubated at 37°C for 24 hours aerobically. The isolates were identified on the basis of colony morphology, Gram staining and appropriate biochemical tests.

All the Aerobic isolates were subjected to antibiotic susceptibility test by Kirby-Bauer disc diffusion technique following standard procedures.14,15 Data regarding age, educational status, parity, personal monthly income, antenatal care, place and mode of delivery, complication during delivery, rupture of membrane, number of vaginal examination, outcome of baby, nature of vaginal discharge and types of Aerobic bacteria from endocervical swabs/secretions were recorded properly.

Results
This study included clinically diagnosed 50 cases of Puerperal sepsis. Blood-stained and foul-smelling vaginal discharges were present in 42 (84%) women, 07 (14%) had purulent and odorous discharge and only 2% has non-odorous watery discharge. (Table I)

Regarding the results of culture, it was found that out of 50 endocervical specimens, 20 (40.0%) yielded growth of Aerobic bacteria, 22 (44.0%) yielded mixed growth, i.e. both
Aerobic and Anaerobic and 08 (16.0%) yielded no growth in culture. (Table II)

Distribution of different Aerobic bacterial isolates were observed and found that *Staphylococcus aureus* was at the top of the list (26, 61.90%). Isolation rate of *Escherichia coli*, *S. epidermidis*, *Streptococcus pyogenes* and *Enterococcus faecalis* were 6 (14.28%), 5 (11.90%), 3 (7.14%) and 2 (4.76%) respectively. (Table III)

Discussion

Puerperal sepsis is an important cause of hospitalization due to its clinical morbidity. Usually the infection is of polymicrobial in origin with a mixture of both Aerobic and Anaerobic organisms. The present study was conducted to see the above parameters in one of the largest tertiary hospitals in Bangladesh where a large number of patients particularly from lower socio-economic condition seek admission for proper management.

An observation by Gibbs (1980) found 58 cases of Endometritis as a complication of vaginal delivery. In another observation conducted in Bangladesh, it was noted that occurrence of foul smelling vaginal discharge remained high (31% up to 2 weeks and 7.1% up to 6 weeks of delivery) in women whose delivery was conducted by untrained personnel at home. Persistent vaginal discharge might be due to prevailing infection either in mild or in severe form. The infectious agents of course are being transmitted from the hands of non-trained personnel including Dais, neighbours or in-laws. Certain practices such as not cleaning the birth canal with water and antiseptic, frequent digital examination with unwashed hands and intra-vaginal application of ghee or other herbal products by untrained health personnel were
found to enhance the risk of vaginal infections.\textsuperscript{19} In the present study, out of 50 endocervical specimens, Aerobic and mixed growth (both Aerobic and Anaerobic) was observed in 40\% and 44\% samples respectively. This finding was compared with a study conducted with transcervical endometrial swabs from 51 women showing Aerobic bacteria from 85.2\% cases following vaginal delivery and 75.1\% following Caeasaran Section, which is not consistent with findings (40\%) of the present study. The study also yielded mixed growth (Aerobic and Anaerobic) in 48.1\% cases that showed very good correlation (44\%) with that of the current study. Because administering prophylactic antibiotic injection or capsule following delivery is almost routinely practiced by rural practitioners or even in hospitals and as this was not perfectly ruled out, this practice may contribute to the lower isolation rate of the Aerobic organisms.

Distribution of Aerobic bacteria as the cause of Puerperal sepsis observed in the present study was in agreement with a study by Chaisil Watana (1991) that showed predominance of (78\%) of Gram positive cocci with 8\% isolates being Gram negative bacteria.\textsuperscript{20} Another study done in UK on 286 women with vaginal swabs found heavy growth of \textit{S. aureus}, Beta Haemolytic Streptococcus (Gr A, C or G), \textit{S. pneumoniae} or \textit{Haemophilus influenzae}.\textsuperscript{21} Pokharel (2004) reported \textit{S. aureus} as the commonest (50\%) organism causing postpartum genital infections in women who delivered their babies with premature rupture of membrane, whereas women who delivered their babies with rupture of membrane in due time developed postpartum genital infections by \textit{E. coli} (28.8\%).\textsuperscript{22}

Other studies done in abroad or in home observed variations in the distribution of Aerobic bacteria causing Puerperal sepsis. In this context, one study done in Sir Salimullah Medical College and Mitford Hospital found \textit{E. coli} as the predominant bacteria (50\%) followed by Staphylococcus species (30\%) and Streptococcus species (20\%).\textsuperscript{23} Distribution of \textit{E. coli}, Staphylococcus species and Streptococcus species in another study done in USA was reported to be 36\%, 28\% and 21\% respectively.\textsuperscript{24} Another study done in Pakistan (Mayo hospital, Lahore) reported isolation rate of Gram positive cocci as 40\% and Gram negative bacilli as 60\% from cases of Puerperal sepsis.\textsuperscript{25} The most common Gram positive bacteria found in the study were \textit{S. aureus}, \textit{S. epidermidis} and Enterococcus. The most common Gram-negative bacteria were \textit{E. coli}, \textit{Klebsiella pneumoniae} and \textit{Pseudomonas aeruginosa}. Anaerobes were equally important.\textsuperscript{26} Other studies from India reported \textit{E. coli} as the most common organism isolated from maternal genital tract followed by \textit{S. aureus} and \textit{K. pneumoniae}.\textsuperscript{26,27} In western country, Group B Streptococcus was found to be the most common organism implicated in maternal genital tract colonization resulting Puerpertal infection of mother and also to babies.\textsuperscript{28} Another study observed that in cases of Puerperal sepsis the most common bacteria were \textit{S. epidermidis}, \textit{E. coli}, Enterococci and Streptococci.\textsuperscript{29}

The variation of bacteria isolated from genital tract causing Puerperal infection as endogenous source may represent regional variation of genital flora.\textsuperscript{27} In addition, the source of infection might be exogenous where pathogens from nearby skin flora or from contact with contaminated instruments, dressings or pads are implanted in the mucosa of genital tract.

In the present study, antimicrobial susceptibility of different Aerobic bacterial isolates was seen. All the strains of \textit{S. aureus} and \textit{S. epidermidis} were sensitive to Cephalexin and Vancomycin. Similarly all the strains of \textit{E. coli} were sensitive to Gentamicin, Amikacin, Ciprofloxacin and Cephalexin. All the strains of \textit{S. pyogenes} were sensitive to Amoxicillin also. All five isolates of \textit{S. epidermidis} (100\%) and majority (84.6\%) of the \textit{S. aureus} strains were sensitive to Ciprofloxacin. All the isolates of Enterococcus were sensitive to Amoxicillin and Cephalexin. Kankuriesko and others (2003) reported that majority of different Aerobic bacteria (81\%) isolated from cases of Puerperal sepsis were sensitive against first and second generation Cephalosporins.\textsuperscript{30} Another study from Nepal also observed that 100\% strains of different Aerobic bacteria were sensitive to Cephalexin.\textsuperscript{32} Findings of the two studies mentioned above were well consistent with results of the present study. \textit{E. coli} and other Gram negative bacteria showed 100\% sensitivity towards Gentamicin in a study by Modi et al (1986) in India that also stood highly comparable to the results of the present study.\textsuperscript{31} Isolates of the genus Staphylococcus in the present study were 100\% susceptible to Vancomycin that was in close accordance with a report from the USA.\textsuperscript{32}

Sensitivity to Ciprofloxacin (Quinolone) among different Aerobic bacteria as found in the present study, well compared with that of the Martens et al (1991) investigating 231 patients of postpartum Endometritis.\textsuperscript{33} In this regard, sensitivity towards second generation Cephalosporins was also consistent with present study results. Isolates of
Enterococcus of the mentioned study also showed >85% strains susceptible to Ampicillin and Gentamicin. In the current study, only 02 strains were identified as *E. faecalis* and were tested against Amoxicillin instead of Ampicillin and found sensitive. The strains were also sensitive to Ciprofloxacin and Gentamicin.

Another study reporting antimicrobial susceptibility of 55 strains of *E. faecalis* from lower genital tract showed that sensitivity towards Carbenicillin, Azlocillin and Ampicillin were 92.7%, 91.2% and 83.9% respectively. The values for resistance of the organism towards Gentamicin and Amikacin were 49.5% and 46.5% respectively.34

Whatever might be the pattern of susceptibility obtained in the present study, property of antibiotic resistance among bacterial population is not a static phenomenon. It is related with magnitude of clinical use, proper dose, adequate duration and close monitoring of bacterial eradication from the site of infection. Despite all the factors having at substandard level in Bangladesh, the susceptibility pattern of Aerobic bacterial strains of the present study is not alarming. On analyzing the findings of the present study, it can be concluded that Puerperal sepsis is the common life-threatening condition in the postnatal period, particularly following vaginal delivery at home. The multiparous, illiterate women from low socio-economic class obtaining no antenatal checkup, bear significant risks for developing Puerperal sepsis.
