Case Report

Fertility-sparing Surgery (FSS) in Epithelial Ovarian Cancer (EOC): A Case Report

SHAHLA KHATUN1, FARZANA DEEBA2, A.B.M. MUKSUDUL ALAM3, ROKSANA IVY4, FARHANA PARVEEN5

Abstract:

Background: Epithelial ovarian cancer is the most common and lethal ovarian cancer. Now a days Fertility preservation is an important issue because of the constant shifting of childbearing age towards higher ages. The increasing incidence of epithelial ovarian cancer in women with active childbearing potential constitutes a therapeutic dilemma. Fertility sparing techniques are being increasingly incorporated in the therapeutic strategies in early stages of the disease. Established organ-preserving techniques in early stage epithelial ovarian cancer includes preservation of the contralateral ovary and uterus.

Aim: To report the case of a Epithelial Ovarian Cancer, who had conservative surgery followed by chemotherapy with a good fertility outcome.

Case presentation: A 31-year-old nulliparous woman with a right sided ovarian mucinous cystadenocarcinoma was treated by right adnexectomy and omentectomy followed by chemotherapy. A 3years follow-up showed no signs of relapse, and she completed a full-term natural pregnancy which was delivered by caesarean section.

Conclusion: Fertility sparing surgery in early stage Epithelial Ovarian Cancer has good prognosis. However, due to the rarity of the disease in early stages, the fertility outcome of this group of patients has not been established.

Keywords: Fertility, Surgery, Mucinous cystadenocarcinoma, Ovary.

Introduction:

Epithelial ovarian cancer is the most common and lethal ovarian cancer1. Fertility preservation is an important issue now a days because of the constant shifting of childbearing age towards higher ages. The increasing incidence of epithelial ovarian cancer in women with active childbearing potential constitutes a therapeutic dilemma2. The abrupt loss of childbearing potential due to the malignant disease is an area of concern both for the patient as well as treating physician. So, alternative treatment options are being sought to preserve a lost hope of fertility within the antitumor treatment5.

Maximal tumor reduction by radical surgery is currently the established cornerstone in the management of advanced epithelial ovarian cancer4. Fertility sparing techniques are being increasingly incorporated in the therapeutic strategies in early stage of disease5. Established organ-preserving techniques in early stage epithelial ovarian cancer includes preservation of the contralateral ovary and uterus or even in highly specialized cases.

peritoniectomy of the pelvis and uterine serosa to avoid the need of hysterectomy are being recruited. The subsequent “fertility protecting” chemotherapy is being applied under the concomitant ovarian protection.

**Case Report:**
A 31-year-old regularly menstruating woman, who was married for three months with no past personal, familial or medical history, admitted in the hospital with acute abdominal pain and deterioration of her general status. After a physical examination, she was found to be afebrile with a whole abdominal tenderness but no signs of peritonitis with an ill-defined lump in hypogastrium. On vaginal examination uterus was found bulky and a mobile tender mass in the pouch of Douglas which was separated from the uterus. The other physical examination findings were normal. Pelvic ultrasound showed a large 10×9 cm right ovarian thick walled complex mass with solid and cystic component within it. The mild vascularity was with a RI +0.43.

In view of her acute abdominal pain, she was scheduled for an emergency laparotomy with a provision of frozen section biopsy. A 10 cm right ovarian mass with intact capsule, without any associated ascites or peritoneal implants was found. The rest of her abdominal cavity appeared normal. A right sided adnexectomy was conducted. The frozen section showed a malignant ovarian tumor. The surgery was completed by omentectomy, biopsy from contralateral ovary and multiple site of peritoneum. A peritoneal washing was obtained immediately after laparotomy. A final histologic examination showed mucinous cystadenocarcinoma with intact capsule. But other specimens were free from malignancy. Final stage of the disease was stage IA.

She was then referred to medical oncologist. The chemotherapy consisting of bleomycin, etoposide, and cisplatin (BEP), with a complete clinical and radiological response after four courses of BEP was obtained. Finally, she underwent six well-tolerated injections of BEP.

Two years post-treatment, follow-up were conducted including physical examinations, ultrasonographic assessment and tumor markers. All these parameters were negative during all follow-up and there have been no sign of relapse up to this date. She also reported a full-term natural pregnancy, which was delivered by caesarean section, 3 years after the completion of the treatment.

**Discussion:**

**Oncologic outcome**
As 70% of epithelial ovarian cancer present at stage III or IV disease few cases have been reported in the literature in early stage disease. As such, the safety of FSS for this disease is accepted but not yet fully clinically supported. Data from the first largest reported series by Zanetta et al. in 1997 concerning oncologic outcome after fertility sparing surgery for epithelial ovarian cancer showed it as a safe treatment option for early-stage disease with acceptable oncologic safety profile.

In 2010, Satoh et al. attempted to systematically determine selection criteria for fertility-sparing surgery in stage I epithelial ovarian cancer. On the basis of clinical outcome of more than 200 stage I patients who underwent fertility-sparing surgery, a relapse rate of 8.5% was reported, among the relapsed cases 27% recurrence was exclusively in the remaining ovary without any distant or peritoneal metastases. While collectively evaluating most published results so far, mean relapse rates are estimated to be around 10%, even in patient’s cohorts which included also Ic stage disease.

**Reproductive Outcome**
In young cancer survivors future fertility prospect represents a therapeutic dilemma for both treating physicians and affected patients. Both the operative and systemic treatments consistently compromise the ovarian reserve and often resulting in infertility and premature menopause. Evidence suggests that the rate of women with successful conception approximately 30% of all patients after FSS. On the contrary the women with an intention to conceive and actively tried to conceive, the rates of successful conception are substantially higher from 66% to 100%, indicating that no relevant reproductive impairment usually exists only for FSS. Assisted reproductive techniques for a successful conception and pregnancy is needed in a small group.

Regarding the incidence of spontaneous abortions, the rates range between 11% to 33%, but no conclusions can be extracted about the cause of the abortions and their pathophysiology in the existing
data. The rates of congenital malformations or abnormal fetal outcomes have been reported in the current literature is not higher\(^9\).

**Conclusions:**
Fertility sparing surgery in early stage Epithelial Ovarian Cancer has good prognosis. It is usually associated with a good fertility outcome in early stages. However, due to the rarity of the disease in early stages, the fertility outcome for this group of patients is not clear. This lack of data surrounding early stages points to the need for a meta-analysis of all published cases.
