ABSTRACT

Detailed histological features of esophagus of 12 Black Bengal goats were studied in the Department of Anatomy and Histology, BAU, Mymensingh-2202, Bangladesh during the period from July to December 2003. All specimens were collected from adult Black Bengal goats (over 6 months of age) irrespective of age and sex. The esophagus of Black Bengal goat was sampled at six mu- tral visceral, middle visceral, caudal cervical, at the level of thoracic inlet, at the middle mediastinum and at the level of cardia. The histological layers of esophagus were: tunica mucosa (lamina epithelia, lamina propria and lamina muscularis mucosa), tunica submucosa, tunica muscularis and tunica serosa adventitiae.

Key words: Histology, esophagus, Black Bengal goat

INTRODUCTION

The esophagus is an important digestive organ in the body. It conveys foodstuffs from mouth cavity to the stomach. Histology of the esophagus of man and different animals was found in the standard texts and literatures (Williams et al., 1995; Bloom and Fawcett, 1968; Cuppethaver et al., 1973; Miller et al., 1966; Gerty, 1975; Dellenmann and Eurell, 1998) but it was revealed that no such study has been performed on the esophagus of Black Bengal goat that is popularly known as “Poor man’s cow” and considered as only the pure breed in Bangladesh. Thus, the present study was carried out to investigate the histological features of the esophagus of Black Bengal goat in Bangladesh.

MATERIALS AND METHODS

Irrespective of age and sex, 12 Black Bengal goats (over 6 months of age) were purchased from local markets and the histological study of esophagus was performed in the Department of Anatomy and Histology, Bangladesh Agricultural University, Mymensingh during the period from July to December 2003. Immediately after slaughtering the goats, samples were collected from six different areas of esophagus-cranial cervical, middle cervical, caudal cervical, at the level of thoracic inlet, at the middle mediastinum and at the level of cardia. The tissues were fixed in 10% neutral buffered formalin then dehydrated in graded alcohol, cleared in xylene, embedded in paraffin and finally the sections were cut at 4μm thickness using rotary microtome. The sections were then stained with standard Hematoxylin and Eosin (H & E) stain. For quantitative estimation, the thickness of tunica mucosa, tunica submucosa and tunica muscularis were measured with the help of calibrated ocular micrometer in 10 random fields in each field in each slide. One small unit of calibrated ocular micrometer had the value of 14.5 μm when the tissues were observed under 10 objectives. Detailed histological study was completed by using medium and low power light microscopy (40X and 10X). Photographs were placed for better illustration of the results.

RESULTS AND DISCUSSION

The esophagus of Black Bengal goat was composed of the following four layers: tunica mucosa, tunica submucosa, tunica muscularis and tunica adventitia (tunica serosa). This observation was similar as described by Williams et al. (1995), Bloom and Fawcett (1968), Cuppethaver et al. (1973) in human, Miller et al. (1966) in dog, Gerty (1975) and Dellenmann and Eurell (1998) in horse and ruminant.

Tunica mucosa

The thickness of mucosa of esophagus of Black Bengal goat was characteristically thrown into longitudinal folds, composed of lamina epithelia, lamina propria, and lamina muscularis mucosa (Fig. 1). The thickness of the layer presented in Table 1.
Lamina epithelia were composed of nonkeratinized stratified squamous epithelium in Black Bengal goat. Lamina propria was composed of dense irregular connective tissue. In loose connective tissue solitary lymphatic nodules were present. Lamina muscularis mucosa was composed of sparsely arranged smooth muscle. This layer was present from cervical esophagus to the cauda of esophagus. Although lamina muscularis mucosa was present throughout the length of the esophagus, it was incomplete and composed of sparsely arranged smooth muscle bundles.

**Typana submaxima**

In Black Bengal goat, **typana submaxima** (Fig. 2) consists of loose connective tissue with many elastic fibers, collagen fibers, blood vessels, and nerves. Esophagogastric glands were found only in cranial cervical region of the esophagus. The thickness of this layer was shown in Table 1.

n = Number of areas, a = Range, b = Mean.

Tunica muscularis

The muscular layer consisted of inner circular and outer longitudinal layers (Fig. 3). Both layers were partially striated. The highest thickness of tunica muscularis was measured 1938.08 µm in the cranial cervical part of the esophagus and the lowest thickness was measured 746.33 µm in the caudal cervical part of esophagus.

The tunica muscularis consisted of smooth muscle throughout the length of the esophagus, whereas Gates (1975) and Delimann and Eustell (1998) stated that cranial and caudal end of esophagus in ruminant composed of smooth muscle.

Tunica adventitia (tunica serosa)

The outer layer of the cervical part of esophagus was termed tunica adventitia. In the thorax, the esophagus was covered by the mediastinal pleura, which formed the tunica serosa. In Black Bengal goats, tunica adventitia was consisted of loose connective tissue with many elastic fibers and had mesothelial lining (Fig. 4).
