Abstract
A controlled clinical trial was conducted in the department of Dermatology and Venereology, Bangabandhu Sheikh Mujib Medical University (BSMMU), Dhaka, Bangladesh to compare the side-effects of adapalene and benzoyl peroxide combination gel with adapalene monotherapy and benzoyl peroxide monotherapy in the treatment of acne vulgaris. The study conducted in sixty patients. Group A (case) 20 patients were treated with adapalene and benzoyl peroxide combination gel, group B (control) 20 patients were treated with topical adapalene and group C (control) 20 patients were treated with topical benzoyl peroxide. The side effects experienced by patients of different groups in their first follow up were noticed. In group A - erythema, scaling, dryness, burning and pruritus were present in 45%, 10%, 35%, 40% and 10% of patients and in group B, 35%, 25%, 30%, 35% and 15% respectively. However in group C dryness and pruritus were absent in all the patients and the erythema, scaling and burning were 30%, 25% and 25% respectively. In 5th follow-up visit, in group A- erythema, scaling, dryness and pruritus were present in 15%, 5%, 15% and 5% of patients respectively and burning was absent in group A. In group B erythema, scaling, dryness, and pruritus were 15%, 5%, 5% and 5% and burning was absent in group B. However in group C scaling, burning, dryness and pruritus were absent in all the patients. Erythema was present in 10% cases in 5th follow-up visit. It was evidenced in the present study that the overall adverse effect is slightly higher with the adapalene- benzoyl peroxide combination therapy in relation to the adapalene and benzoyl peroxide (BPO) monotherapies in the treatment of acne vulgaris.

Key words: Adapalene, Benzoyl peroxide, Acne Vulgaris.

Introduction
Acne vulgaris is a chronic inflammatory disease of the pilosebaceous follicles that occurs primarily in adolescents. Most cases of acne consist of comedones, papules, pustules, and nodules. Although the course of acne may be self-limiting, the sequelae can be life long, with pitted or hypertrophic scar formation.¹ Lesions of acne vulgaris can be divided into non-inflammatory (open and closed comedones) and inflammatory (papules, pustules and nodules).² Overgrowth of the bacteria can lead to precipitation of an innate immune response and in some cases, rupture of follicular wall may occur initiating a host inflammatory reaction leading to inflammatory acne.³⁴ Accordingly, antimicrobial agents have been a mainstay of acne therapy targeting P. acne colonies.⁵ In acne, the host response to P. acnes can result in the production of proinflammatory

cytokines, such as tumor necrosis factor-α (TNF-α), interleukin (IL)-1 α, and IL-8 and contribute to the clinical manifestations of the disease. 3,4

Topical treatments are generally recommended for mild to moderate acne. The most frequently prescribed products are retinoids and benzoyl peroxide.6 Adapalene is the 3rd generation retinoid. The chemical name of adapalene is 6-[(3-(1-adantyl)-4-methoxyphenyl) -2-napthoic acid. These agents target comedogenesis by normalizing desquamation of the follicular epithelium, preventing the formation of new micro-comedo precursor lesions, thus minimizing the formation of both inflammatory acne lesions and comedones.7 During the first month of therapy adverse effects like erythema, scaling, burning sensation, stinging sensation, dryness and irritation, pruritus, acne flares etc are most commonly encountered.8 Benzoyl peroxide is frequently used as a first-line therapy for mild to moderate acne. Benzoyl peroxide acts through oxidation and formation of free radicals causing a reduction of P. acnes. This mechanism helps to prevent an induction of resistance in P. acnes often observed during long term acne treatment with antibiotics. However, benzoyl peroxide can cause skin irritation and drying 9 and in 1% of patients, contact allergy may develop.10 Redness, desquamation and burning of treated skin are the dose dependent major symptoms of therapy.11 The present study was therefore aimed to explore the side-effects of adapalene 0.1% and benzoyl peroxide (BPO) 2.5% combination gel compared to adapalene 0.1% monotherapy and benzoyl peroxide (BPO) 2.5% monotherapy in the treatment of acne.

Methods

A controlled clinical trial was conducted in the department of Dermatology and Venereology at Bangabandhu Sheikh Mujib Medical University, Dhaka during the period of September 2010 to February 2011. The study encompassed enrolment of a total of 60 patients. Purposive type sampling technique was followed in this study and data were collected in the structured questionnaire.

Group A (case) 20 patients were treated with adapalene and benzoyl peroxide combination gel, group B (control) 20 patients were treated with topical adapalene and group C (control) 20 patients were treated with topical benzoyl peroxide. Inclusion criteria were: patients clinically diagnosed as acne vulgaris, having age ≥12 years and of both sexes, patients with non-inflammatory (comedones) lesions and inflammatory (papules, pustules) lesions on the face and female who were not on oral contraceptive pill. Exclusion criteria were: patients suffering from nodulo-cystic acne, pregnant women and lactating mother, persons having hypersensitivity to adapalene and benzoyl peroxide and patients with other dermatologic conditions interfering with the treatment of acne vulgaris.

Ethical Issues

All patients were given an explanation of the study including the potential risks and obtainable benefits. Patients were included in the trial after taking their informed consent. They were explained about the right to refuse or accept to participate in the study. All patients were ensured that all data obtained during study period will be kept confidential.

Procedure of data collection

A total number of sixty patients were primarily selected and they were randomized using computer-generated codes into three groups (group-A and group-B & group-C). Complete history, general physical examination and dermatological examinations were done for all enrolled patients. For women of reproductive age reproductive history, menstrual history, lactation and pregnancy plan were carefully judged. History and physical findings were recorded in a structured questionnaire. Finally those patients, who matched the inclusion and exclusion criteria according to history, physical examination and freely gave their informed consent, were selected for the study. Patients were divided into three groups. The first group was given adapalene and benzoyl peroxide combination gel once daily in the evening for 12 week. The second and third groups were given adapalene cream and benzoyl peroxide cream respectively. Patients were clinically assessed at baseline...
and at week 1, 2, 4, 8 and 12. The patients included in this study were prescribed the generic formulation of adapalene and benzoyl peroxide combination gel, topical adapalene and topical benzoyl peroxide, which are available in the market.

Data processing and analysis

Data analysis was performed by Statistical Package for Social Science (SPSS), version-12. Data were edited, coded and entered into the computer. Statistical analyses were done and level of significance was measured by using appropriate procedures like chi square test ($\chi^2$), relative risk (RR) measurement, t-test, proportion (d) test, ANOVA tests and others where applicable.

Results

Total 60 patients were enrolled. Group A (case) 20 patients were treated with adapalene and benzoyl peroxide combination gel, Group B (control) 20 patients were treated with topical adapalene and Group C (control) 20 patients were treated with topical benzoyl peroxide. Table 1 reveals the mean age of group A, group B and group C patients were 21.50 ± 3.32, 21.55 ± 4.12 and 22.25 ± 4.67 respectively. There was no significant difference of age between the groups. In group A and B 40% of the patient were male and 60% were female patient. In group C 45% were male patient and 55% were female patient.

The side effects experienced by patients of different groups in their first follow up were shown in figure I. In group A - erythema, scaling, dryness, burning and pruritus were present in 45%, 10%, 35%, 40% and 10% of patients respectively. In group B - erythema, scaling, dryness, burning and pruritus were 35%, 25%, 30%, 35% and 15%. However in group C - dryness and pruritus were absent in all the patients and the erythema, scaling and burning were 30%, 25% and 25% respectively. Table 2 represents side effects of the 5th follow-up visit. In group A - erythema, scaling, dryness and pruritus were present in 15%, 5%, 15%, and 5% of patients respectively, and burning was absent in group A. In group B erythema, scaling, dryness, and pruritus were 15%, 5%, 5% and 5% and burning was absent in group B. However in group C scaling, burning, dryness and pruritus were absent in all the patients and the erythema were present in 10% cases in 5th follow-up visit.

Discussion

A total of sixty patients were primarily selected based on inclusion criteria of the study and randomly assigned to one of the three groups (group A, group B and group C). Acne vulgaris is a common skin disorder that is experienced by most people at some stage during their lifetime. It accounts for approximately 25% of patient visits in private
Overall, the safety and tolerability results of enrolled in a 2:2:2:1 ratio, respectively. For 12 weeks involved 517 acne patients BPO 2.5% gel or the gel vehicle used nightly 0.1% + BPO 2.5% gel, adapalene 0.1% gel, study was conducted in which adapalene relative to the monotherapies. Occurrence of adverse effects was slightly higher with the combination therapy compared with adapalene and BPO was significantly greater safety for the treatment of acne vulgaris as early as week 1 relative to monotherapies, with a comparable safety profile to adapalene. Earlier studies have shown that adapalene can be added to other therapies without significantly increasing skin irritation.

A subsequent larger Phase III double-blind, randomized-controlled trial (RCT) with similar trial design involving 1668 patients randomized into the same 4 treatment arms in a 1:1:1:1 ratio was performed in 2009. Over all, more patient in adapalene-BPO combination experienced local tolerability signs and symptoms compare to monotherapy. However, these were transient and mostly mild to moderate in severity. The most frequent treatment-related adverse event was dry skin, which was higher in the combination and adapalene groups than in the BPO monotherapy and vehicle groups (i.e., 6.0%, 4.3%, 1.9%, and 2.2% respectively).

A trans-Atlantic randomized, double-blind, controlled study was carried in patients 12 years of age and older with moderate facial acne vulgaris rated on the Investigator’s Global Assessment (IGA), 20 to 50 inflammatory lesions(IL) and 50 to 100 non-inflammatory lesions(NIL) for 12 weeks (1:1:1:1 randomization). The local cutaneous tolerability of adapalene–BPO was comparable with adapalene and BPO was good for all treatments, with all mean tolerability scores at each visit and worst post baseline scores for erythema, dryness, scaling, and burning/stinging less than 1 (mild). A majority of subjects in all of the groups experienced mild or no irritation. Mean tolerability scores, based on erythema, scaling, dryness, and stinging/burning, peaked at the first week and declined thereafter. They concluded that fixed-dose combination of adapalene and BPO provides significantly greater safety for the treatment of acne vulgaris as early as week 1 relative to monotherapies, with a comparable safety profile to adapalene. Earlier studies have shown that adapalene can be added to other therapies without significantly increasing skin irritation.
compared to vehicle and the adapalene and BPO monotherapies.  17
A three weeks, randomized, controlled, investigator-blinded, single-center, bilateral (split-face), dose assessment study was done comparing the cutaneous tolerability of adapalene-BPO fixed dose combination products versus various concentrations of BPO monotherapy applied once daily. Sixty patients were randomized to one of the following treatment groups: adapalene 0.1%-BPO 2.5% combination products versus 2.5 % BPO monotherapy; adapalene 0.1%-BPO 2.5% combination products versus 5% BPO monotherapy; adapalene 0.1%-BPO 5% combination products versus 10 % BPO monotherapy. Assessments included total sum score (TSS) of irritation signs / symptoms (erythema, scaling, dryness, pruritus, stinging/burning). The overall cutaneous tolerability profile of the adapalene 0.1%-BPO2.5% combination was better than the combination with BPO 5% and similar to BPO 2.5% or 5% monotherapy. The combination product with BPO 5% induced significantly more irritation than BPO 5% (P<.001) or BPO 10% monotherapy (P=.001).
In conclusion, the new fixed-dose adapalene 0.1%-BPO 2.5% combination gel provided the better overall cutaneous tolerability profile relative to other combination.  18

Conclusion
It is evidenced from this study that the overall adverse effect is slightly higher with the adapalene-benzoyl peroxide combination therapy relative to the adapalene and benzoyl peroxide (BPO) monotherapies in the treatment of acne vulgaris. These adverse effects were transient and minor in nature, no-patients had to discontinue the treatment for adverse effects and most of the adverse effects were remitted spontaneously without treatment. The clinicians are advised to take into account the adverse effects of therapies encountered whey they prescribe.
