Abstract:

Sertoli-Leydig Cell Tumor (SLCT) is an extremely rare and distinctive sex cord-stromal tumor. Ovarian sex cord-stromal tumors are infrequent tumors that differ from the more frequent epithelial neoplasm and have strong association with hormone-mediated syndromes, presentation in a wide age range, and the diagnosis is usually at early-stage disease with a good outcome. SLCT typically present with pelvic or abdominal pain and tenderness, mass, and or abnormal menstruation, and with hormonal activity reported predominantly after menarche. We report a case of 18-year-old unmarried female presented with severe pain and lump in the lower abdomen and also a case of primary amenorrhea with normal secondary sex characters. She was a suspected case of twisted ovarian tumor on USG and underwent laparotomy followed by total excision of the lump and histopathology report revealed Sertoli-Leydig Cell Tumor. Though it is a rare tumor, the possibility of Sertoli-Leydig Cell Tumor in a young woman should be kept in mind.

Key words: Ovarian tumor, Sex cord-stromal tumor, Sertoli-Leydig Cell Tumor.

Introduction:

Ovarian sex cord-stromal tumors are uncommon neoplasms that represent approximately 7% of all ovarian tumors. These tumors comprise a heterogeneous group and are formed by diverse cell type that arises from the primitive sex cords or stromal cells. The stromal cell includes theca cells, fibroblasts, and Leydig cells whereas the gonadal primitive sex cords include granulosa cells and Sertoli cells. These cell types may be present separately or admixed and display different degrees of differentiation.

Sertoli-Leydig Cell Tumor is an extremely rare ovarian neoplasm that accounts for approximately 0.5% of all ovarian tumors. According to WHO classification scheme for ovarian sex cord-stromal tumors (2014), it is included in the mixed sex cord-stromal tumors which may be well-differentiated to poorly-differentiated with heterologous elements, and retiform with heterologous elements.

Approximately 75% of the SLCTs are encountered in women of younger age usually less than 30 years. However, few cases have been described in postmenopausal women. For SLCT, nearly all cases are unilateral (98%) and 80% are confined to ovary at diagnosis. SLCT is the most common virilizing tumor, as approximately 30-50% of these tumors produce androgens (testosterone & androgens precursors) and more than one-third of cases develop symptoms of virilization and amenorrhoea.

SLCT is a rare cause of virilization in premenopausal women. In this age group, other differential diagnosis such as PCOS and adrenal androgen producing tumors should be considered.

Many SLCTs are hormonally inactive and a small sub group is estrogenic. Sudden abdominal pain and swelling are frequent symptoms of non-functioning tumors. Very rarely, SLCT have been reported to associate with elevated alpha-fetoprotein serum levels; this is a typical feature of germ cell tumors such as yolk sac neoplasm.

The prognosis of SLCT is good and 92% of tumors manifest at early stage i.e. at stage-1. The most important prognostic factors are the stage and degree of differentiation.
histologic differentiation\textsuperscript{3,6,10}. In a previous report by Sigismondi et al., five year survival rates of 92.3\% and 33.3\% were reported for patients with stage 1 and stage $\geq 2$ disease, respectively\textsuperscript{11}. In the same report, patients with well-differentiated tumors had a five-year survival rate of 100\% versus 77.8\% for patients with moderately and poorly differentiated tumors. In contrast to Germ Cell Tumors, which tend to recur late, malignant SLCTs usually recur early in the pelvic and abdominal cavity with a reported relapse rate of 71.4\% within two years after diagnosis\textsuperscript{11}.

**Case Report:**

An 18 years old unmarried girl was admitted in the inpatient department of obstetrics and gynecology of Rangpur Medical College Hospital with the complaints of severe pain and lump in the lower abdomen. Her menstruation was yet not established. On clinical examination, she was 162.5 cm tall, weight 50 kg, B.P 100/60 mm of Hg, breasts were developed, and axillary and pubic hair were present with female type of distribution, and external genitalia and introitus were present. A tender mass was palpable about 10×9 cm located in lower abdomen, surface irregular and ill defined margin with restricted mobility. Bimanual examination was done gently with one finger and found cervix absent and uterus could not be well delineated. Digital Rectal Examination was also done gently and findings corresponded with that of bimanual examination. Ultrasonography revealed size and shape of the uterus that was not well defined and a well defined complex, predominantly solid mass with small cystic component about (108×93) mm was noted in left adnexal region. Tumor markers could not be done due to shortage of time as it was an emergency. On laparotomy, uterus could not be delineated rather it was found as a fibrosed band like structure. Both sided fallopian tubes were present and a partly solid and partly cystic mass of about (10×10) cm was found on the right adnexal region which was adherent with fibrosed band and omentum but left ovary could not be visible separately which may be buried or adherent with right ovarian mass. There was no ascites. After total excision of the mass, both the fallopian tubes, fibrous band was also removed and partial omentectomy was done (which was apparently healthy looking i.e. no seedling or cake like feelings), and specimens were sent for histopathology. Postoperative period was uneventful and the patient was discharged on 5\textsuperscript{th} postoperative day.

**Histopathology Report:**

**Gross examination**

1. Tissue from ovary: Part of cyst wall measured 3×2 cm with maximum thickness of 0.5 cm. Cut surface was grayish white.
2. Tissue from omentum: Fibrofatty tissue measured 4×3×2 cm. Cut surface was grayish yellow.

**Microscopic examination:**

1. Section showed features compatible with Sertoli-Leydig cell tumor with area of necrosis and calcification.
2. Edematous and congested fibro fatty tissue with focal mesothelial proliferation and infiltration of inflammatory cells.

**Figure-I:** USG showed a well defined complex predominantly solid mass with small cystic component.

**Figure-II:** Microscopic view of moderately differentiated Sertoli-Leydig cell tumour
Discussion:

Sertoli-Leydig Cell Tumor is mixed sex cord-stromal tumor, described as a distinct entity in 1973 by Chalvardjian and Scully\textsuperscript{12}. Ovarian Sex cord stromal tumors are uncommon neoplasm that represents approximately 7% of all ovarian tumors\textsuperscript{1} and SLCT comprises less than 0.5% of all ovarian tumors. This extremely rare tumor characteristically differentiates itself from others both clinically and histologically. The reported mean age is 23-25 years in different studies\textsuperscript{13}. The well-differentiated tumors occur at an average age of 35 years and retiform tumors at an average age of 15 years\textsuperscript{14}.

About one third of patients with SLCT have androgenic manifestations including: oligomenorrhoea, hirsutism, hoarseness, breast atrophy, and clitoral hypertrophy. Approximately half of patients with SLCT have no endocrine manifestation and mainly experience abdominal swelling and pain. Occasional patients have been represented with estrogenic manifestation, including irregular menstruation or menorrhagia in women in the reproductive age group and postmenopausal bleeding in older women. Well-differentiated tumors occur at an average age of 35 years and retiform tumors at an average age of 15 years\textsuperscript{15}.

In our case, the patient was presented with severe pain and lump in the lower abdomen and USG revealed ovarian tumor, so provisional diagnosis was twisted ovarian tumor and emergency laparotomy was done at evening period. The patient gave the history of primary amenorrhea and on clinical examination secondary sex characters were present, on bi-manual and digital rectal examination cervix was absent and uterus could not be well delineated. USG also could not delineate the uterus properly. Tumor markers could not be carried out as facilities were not available in the hospital and the patient was too poor to afford the cost privately. CT scan also could not be done as it was an emergency and not on office hour. On laparotomy, a fibrous band was found instead of uterus and both sided fallopian tubes were present and a partly solid and partly cystic mass of about (10×10) cm was found on the right adnexal region which was adherent with fibrosed band, posterior and lateral pelvic walls and omentum but left ovary could not be visible separately which may be buried or adherent with right adnexal mass. Total excision of the mass, fibrous band and both fallopian tubes and omentectomy was done, and specimens were sent for histopathology.

After confirmation of SLCT on histopathology, patient was advised for consultation with oncologist for further treatment but the patient was non-compliant for further treatment (chemotherapy) and follow-up which may be due to poverty, illiteracy or unawareness. Unfortunately the patient died after two months of operation.

Conclusion:

Ovarian sex cord-stromal tumors are infrequent tumors that differ considerably from the more frequent epithelial ovarian tumors. The rarity of sex cord-stromal tumor contributes to a low index of suspicion;
therefore, a thorough knowledge of the clinico-pathologic and advanced radiologic and imaging findings of these tumors is important. The prognosis of patients with grade 1 SLCT is excellent without adjuvant chemotherapy and that of advanced stage or grade 2-3 tumors appear to benefit from postoperative chemotherapy.
