ABSTRACT

The platinum-poly-yne polymers poly\[trans-bis(tri-n-butylphosphine) platinum-poly (4,4’-diethynylenearylene)\] (arylene = biphenylene 3 and anthracene 4) were synthesized by the condensation reaction between poly(diethynylenearylene) (arylene = biphenylene 1 and anthracene 2) and trans-\{(P\textsubscript{3}Bu\textsubscript{3})\textsubscript{2}PtCl\textsubscript{2}\} in disopropyl amine and dichloromethane under nitrogen atmosphere in the presence of CuI catalyst. The newly synthesized platinum containing poly-yne polymers exhibit good solubility in common organic solvents. These metal linked polymers were characterized by IR, \textsuperscript{1}H NMR and \textsuperscript{31}P NMR spectroscopy.

Key words: Platinum-poly-yne polymer, Conjugated organic polymer, Hay’s oxidative coupling, Condensation

INTRODUCTION

Metal containing poly-ynes are of current research interest due to the potential for combining the characteristics of transition metals and conjugated organic polymers within one material (Molapo et al. 2012, Cyr et al. 2005). The conjugated σ-bonded acetylide complexes and their metallated derivatives with a wide domain of intriguing properties are very useful for the development of optoelectronic devices, such as, organic light emitting diodes (OLEDs), photovoltaic cell, field effect transistors (FET), sensor and non linear optical materials (Long et al. 2003). Owing to their rigid rod linear structure, they also behave as liquid crystals (Amato et al. 2004). These properties depend on the fragments of the poly-ynes: (a) metals, (b) auxiliary phosphine ligand and (c) σ-bonded acetylide ligands (Long et al. 2005). The structure of organometallic polymers (Fig. 1) can be modified by changing the metal, the auxiliary ligands, or the spacers (Younus et al. 1998).

Organometallic polymers containing Group 8 - 10 metals in the backbone are highly soluble in common organic solvents and these polymers are stable in air. Polymer
stability is one of the most important criteria for their application as conducting polymers in various practical devices (Alsalhi et al. 2011). Due to the presence of d-orbitals in the metal, conjugation in these polymers can be maintained through the metal centre. Some metal-poly-yne polymers were designed by using the concept of alternating donor and acceptor units (Younus et al. 1998).

In recent works, the authors reported the synthesis of platinum-polyynes with phosphines other than tri-n-butylphosphine. These include platinum ethynyl complexes with 1,2-bis(diphenylphosphinoethane), dppe, cis-[Pt(dppe)(C≡C-C_6H_4-p-C ≡CH)], cis-[Pt(dppe)(C≡C-C_6H_4-p-C ≡CH)], cis-[Pt(dppe)(C≡C-C_6H_4-p-C ≡CH)], cis-[Pt(dppe)(C≡C-C_6H_4-p-C ≡CH)], cis-[Pt(dppe)(C≡C-C_6H_4-p-C ≡CH)] (Saha et al. 2005) and tri-tolylphosphines containing platinum poly-yne polymers i.e. [-Pt(p-toly13P)_2C ≡C-R-C ≡C-]n, (R=biphenyl and 2,5-dioctyloxybenzene) (Sina et al. 2014). The synthesis of platinum end-capped poly(aryleneethylene)s - [Ph(P^Bu_3)_2Pt-C ≡C-(Ar-C ≡C-C ≡C)n-Pt((P^Bu_3)_2Ph] {Ar = C_5H_5N, C_6H_6, C_6H_4(CH_3)_2, C_6H_4-C_6H_4} has also been reported (Hossain et al. 2011).

The authors report the synthesis of a series of extended poly-ynes where platinum is in the main chain. The molecular structure of newly synthesized metal poly-ynes is shown in Fig. 2.

**MATERIALS AND METHODS**

*Trans*-[(P^Bu_3)_2PtCl_2], Copper(I)iodide, copper(I)chloride, and tetramethylethylene-diamine (TMEDA) were purchased from Aldrich, Germany. The starting materials 4,4’-
diethynylphenyl, 4,4'-diethynylbiphenyl (Xu et al. 2012) and 9, 10-diethynylenanthracene (Baier et al. 2009) were prepared by the methods previously reported. All the solvents dichloromethane (CH₂Cl₂), disopropylamine (Pr₂NH) and tetrahydrofuran (THF) were purchased from Merck, Germany. Alumina for column chromatography (Aluminium oxide 90 active, neutral, 70-230 mesh ASTM, particle size 0.063 - 0.02120), k and thin layer chromatography (TLC) plates were also purchased from Merck, Germany.

The Infrared spectra of all the compounds were recorded on KBr pellets with a SHIMADZU IR spectrometer (Prestige 21). Standard ¹H NMR and ³¹P NMR spectra were recorded on a BRUKER 400M Hz NMR spectrometer, at BCSIR, Dhaka, Bangladesh.

**Synthesis of mL (4,4'-diethynylenebiphenylene) 1:** Poly(4,4'-diethynylenebiphenylene) 1 were prepared by the adaption of the synthetic route reported by Kloppenburg et al. 1999. Freshly distilled and dried THF (20 mL) were added into CuCl (0.010 g) and TMEDA (N, N, N', N'-tetramethylethylenediamine) (0.015 g), and the reaction mixture was bubbled by oxygen gas for 10 minutes. A solution of 4,4'-diethynylbiphenyl monomer (0.050 g, 0.247 mmol) in 5 mL THF was then added to the reaction, and it was stirred for 24 hours at room temperature under oxygen atmosphere. A pale yellow colored precipitate was formed in the flask. The crude product was purified by washing it with MeOH-HCl, then with methanol, and dried under vacuum. Yield 95% (0.047g). IR (cm⁻¹): ν (C≡C), 2106; ν (aromatic C=C), 1602 and 1489; ν (aromatic C-H), 3066; ν (≡C-H), 3286.

**Synthesis of poly(9, 10-diethynylenanthracene) 2:** The procedure for 1 was followed, but using 9,10-diethynylenanthracene (0.01 g) instead of 4,4'-diethynylenebiphenylene to give Poly(9, 10-diethynylenanthracene). 75% yield (0.075
g). IR (cm\(^{-1}\)): ν (C≡C), 2096; ν (aromatic C=C), 1670 and 1489; ν (aromatic C-H), 3059; ν (≡C-H), 3278.

**Synthesis of poly[trans-bis(tri-n-butylphosphine)platinum poly (4, 4’diethynylene-biphenylene) 3**: To a mixture of freshly distilled, dried and degassed diisopropylamine (10 mL) and dichloromethane (20 mL) trans-\{P\(^3\)Bu\(_3\)\}_2PtCl\(_2\) (0.0186 g), poly(4,4’-diethynylenebiphenylene) 1 (0.05 g) and copper(I) iodide (10 mg) were added and it was stirred at 68°C temperature for 48 hours under nitrogen atmosphere. Then the solvents were removed under reduced pressure, and the crude polymer was extracted with dichloromethane and dried under vacuum. The product was purified column chromatography over alumina using dichloromethane and methanol (30 : 1) as eluent. Yield 75% (0.024 g). IR (cm\(^{-1}\)): ν (C≡C), 2096; ν (aromatic C=C), 1541 and 1486; ν (aromatic C-H), 3029; ν (methyl C-H), 2910; ν (Pt-C) 668. \(^{1}\)H NMR (CDCl\(_3\), δ ppm): 0.89 (m, -H\(_3\)\(^1\), nBu), 1.18 (m, -CH\(_2\)CH\(_3\), nBu), 1.41 (m, -CH\(_2\)CH\(_2\)CH\(_3\), nBu), 2.16 (m, -CH\(_2\)CH\(_2\)CH\(_2\)CH\(_3\), nBu) multiplet at δ 7.46-7.56 (m, benzene ring). \(^{31}\)P NMR: one singlet at 4.67 with two satellite at δ 11.96 and -2.58 (\(J_{Pt-P}\))= 2355 Hz.

**Synthesis of poly[trans-bis(tri-n-butylphosphine)platinum poly(9,10-diethynyleneanthracene) 4**: The procedure for 3 was followed but using poly(9,10-diethynyleneanthracene) 2 (0.05 g) instead of poly(4,4’-diethynylenebiphenylene) 1 to give poly[trans-bis (tri-n-butylphosphine) platinum poly(9,10-diethynyleneanthracene)] 4. Yield 69% (0.047g). IR (cm\(^{-1}\)): ν (C≡C), 2085; ν (aromatic C=C), 1465; ν (aromatic C-H), 3029; ν (methyl C-H), 2958; ν (Pt-C) 668. \(^{1}\)H NMR (CDCl\(_3\), δ ppm): 0.88 (m, -CH\(_3\), nBu), 1.25 (m, -CH\(_2\)CH\(_3\), nBu), 1.53 (m, -CH\(_2\)CH\(_2\)CH\(_3\), nBu), 2.17 (m, -CH\(_2\)CH\(_2\)CH\(_2\)CH\(_3\), nBu) multiplet at δ 7.52-8.76 (m, benzene ring). \(^{31}\)P NMR: two singlet at δ 2.23 with satellites 9.13 and -4.81 and at δ -6.69 with satellites 0.25 and -13.63.

**RESULTS AND DISCUSSION**

The organic polymers (1 and 2) were synthesized by Hay’s oxidative coupling reactions which were reported by Hossain et al. 2011. The metal-poly-yne polymers 3 was synthesized (Scheme 1) by the condensation reaction between trans-\{P\(^3\)Bu\(_3\)\}_2PtCl\(_2\) and organic polymers 1, in diisopropylamine and dichloromethane (1 : 2) using CuI as a catalyst. Poly-yne 4 was formed similarly.

The insoluble nature of the conjugated organic polymers 1 and 2 limits their characterization by standard spectroscopic techniques (Hattori et al. 1997). Present authors introduced platinum metal in the polymeric chain to increase its solubility and to diversify practical applications. These metal poly-yne polymers were purified by column chromatography, and characterized by IR, \(^{1}\)H NMR and \(^{31}\)P NMR spectroscopy. All these metal-poly-yne polymers 3 and 4 were pale yellow colored and obtained in high
percentage (3 - 75, 4 - 69) of yield. As expected the resulting metal poly-yne polymers 3 and 4 were highly soluble in common organic solvent including CH₂Cl₂ and CHCl₃.

\]

In IR spectra, the ν(C≡C) stretching frequency is diagnostic of the characterization of metal poly-yne polymers, and useful in following the course of reaction. IR spectra of organic polymers 1 and 2 displayed a peak at 3286 and 3278 cm\(^{-1}\) due to the presence of terminal acetylenic hydrogen (≡C-H str.) group, and the bands at 2096 and 2094 cm\(^{-1}\) for the (C≡C str.). But metal poly-yne polymers 3 and 4 showed no peak in the range 3200 - 3300 cm\(^{-1}\) terminal acetylenic hydrogen (≡C-H str.) indicating the formation of Pt-C≡C bond. After metal incorporation the C≡C bond stretching frequency is shifted from 2106 to 2096 cm\(^{-1}\) for 3 (Fig. 4) and 2094 to 2085 cm\(^{-1}\) for 4 which is the characteristics of Pt(II)-poly-yne polymers. This may be attributed to either (i) the metal-to-alkyne π backbonding or (ii) the M\(^{\text{II}}\)-C\(^{\delta}\) bond polarity (Lewis et al. 1997).
Fig. 4. Comparison IR (KBr) spectra of poly-ynes 1 and 3.

$^1$H NMR spectrum of polymer 3 (Fig. 3) displayed multiplet at δ 0.89, 0.94, 1.18, and 1.41 due to the $\text{-CH}_3^1$, $\text{-CH}_2^2\text{CH}_3$, $\text{-CH}_2^3\text{CH}_2\text{CH}_3$, $\text{-CH}_2^4\text{CH}_2\text{CH}_2\text{CH}_3$ proton resonances of n-butyl and multiplet at δ 7.46 - 7.56 indicating the proton in the benzene ring. Polymer 4 (Fig. 3) displayed similar $^1$H NMR signals in the expected region. Sharp signals were not observed due to the oligomeric mixture present in poly-ynes (Hossain et al. 2011).

For all the Pt(II) poly-ynes, the $^{31}$P NMR spectra contained signals with the expected satellites due to the coupling of $^{31}$P nuclei with the $^{195}$Pt. In the $^{31}$P NMR spectrum of polymer 3, a singlet at 4.67 and two satellites at δ 11.96 and -2.58 were displayed with coupling constant of $J_{P,P} = 2355$ Hz. This coupling constant value is consistent with a trans-square planar complex, and reflect the greater trans influence of the alkynyl ligands compared to the chloride. (Saha et al. 2005). Polymer 4 displayed one singlet at δ 2.23 with satellites 0.25 and -13.63. In addition, signals at 2.23, 9.13, and 4.81 of 4 indicate different molecular weight oligomers with high polydiversity. Another metal poly-yne polymer was synthesized using poly(4,4'-diethynylenephenylene) polymer. The $^{31}$P NMR spectrum of polymer poly[trans-bis(tri-n-butylphosphine) platinum poly (4,4'-diethynylenephenylene)] showed signals at 7.84, 4.74, 0.52 and -11.23 ppm, but no satellites were observed. This indicates depolymerization of the Pt(II) poly-ynes in CDCl$_3$ solvent.
Condensation reaction is a very effective process for the synthesis of metal-poly-yne polymers. Though conjugated organic polymers 1 and 2 are insoluble in common organic solvents, but the metal-poly-yne polymers 3 and 4 exhibit good solubility. The metal-poly-yne polymers poly[trans-bis(tri-n-butyl phosphine)platinum-poly(4,4’-diethynylenebiphenylene)] 3 and Poly[trans-bis (tri-n-butylphosphine) platinumpoly (9,10-diethynyleneanthracene] 4 were synthesized by the condensation reaction between poly(diethynylenearylene) {arylene = biphenylene 1 and anthracene 2} and trans-[(PnBu3)2PtCl2] in diisopropyl amine and dichloromethane under nitrogen atmosphere in the presence of CuI catalyst. These metal poly-yne polymers were purified by column chromatography, and characterised by IR, 1H NMR and 31P NMR spectroscopy.
