Epidemiological & Clinical Profile of Patients Presented with Mandible Fracture in a Tertiary Care Hospital

F SULTANAa, MR KARIMb, IA HAIDERC

Summary:
Mandible is the second most commonly fractured bone after nasal bone, though it is the largest and strongest facial bone. Fractures of the mandible can involve only one site or can often involve multiple anatomic sites. It account for 36% to 59% of all maxillofacial fracture. The large variability in reported prevalence is due to a variety of contributing factors such as gender, age, environment, and socio-economic status of patient, as well as the mechanism of the injury. The most favorable site of fracture (in descending order) in mandible is the body, angle, condylar region, symphysis, and coronoid process.

The descriptive type of cross sectional retrospective study was undertaken to determine the epidemiological & clinical profile of patients presented with fractures of mandible and their different methods of treatment modalities. Four hundred and thirty five patients with mandible fractures were treated during the year 2014-2015. A review of patient's record was conducted. Data regarding age, gender, cause of fracture, anatomic site and treatment modalities were reviewed. There was higher prevalence in male (3.9:1), with occurrence peak between 21-30 years. The principal causes of fracture in this study were RTA (Road Traffic Accidents) representing 54.02% followed by physical assault 17.24%, Fall, Sports injury, Blow by heavy objects, Tube well injury & others which includes Tire blast injury, Gunshot injury, Iatrogenic cause, Pathological fracture, Boat handle injury, Penetrating injury by metal etc. The most injured sites were in parasympysis (26.31%) followed by angle of mandible 17.89% then symphysis, condyle, body of mandible, dentoalveolar, ramus, coronoid process of mandible. Most patients (70.11%) of mandible fractures were treated by closed reduction (arch bar, arch bars with intermaxillary fixation IMF, eyelet wiring & lateral compression plate) & 21.83% of patients were treated with open reduction (miniplates fixation, 3D plate fixation). Only 8.05% patients were managed by conservative approach. This study reflects patterns of mandible fracture within the community and discuss various methods of mandible fracture management in the department of Maxillofacial casualty in Dhaka Dental college hospital. It is hoped that information presented here will be useful to the government agencies and health care professionals involved in planning future programs of prevention & treatment of mandible fracture.

Key words: Epidemiology, clinical profile of mandible fracture, treatment modalities.

Introduction:
The mandible is the area of the face with major incidence of fracture. Its prominence and position in the skeletal face predispose to frequent traumas. Mandible is the second most commonly fractured bone after nasal bone, though it is the largest and strongest facial bone. Mandible fractures can involve only one site or can often involve multiple anatomic sites simultaneously.

The etiology and pattern of mandible fractures vary considerably among different study populations. Recent overall shift in the mechanism of injury and age distribution of patients sustaining these injuries are well-documented. There is reported variability in the pattern of fractures of mandible resulting from different causes of injury, such as road traffic accidents (RTAs), assaults, and falls. Increased frequencies of RTA and domestic violence have emerged as the etiological factors in mandible fractures in developing countries like India. Furthermore, there is an increase in the proportion of adolescent and young adults sustaining this injuries:

Mandible fractures may lead to deformities be them by displacement or non restored bone losses, with dental occlusion affection or temporomandibular joint

disorder. If not identified or inappropriately treated, these lesions may lead to severe squeals, both cosmetic and functional.\textsuperscript{5,6}

It has been reported that fractures of the mandible account for 36\% to 59\% of all maxillofacial fracture.\textsuperscript{7} The large variability in reported prevalence is due to a variety of contributing factors such as gender, age, environment, and socio-economic status of patient, as well as the mechanism of the injury. The most favorable site of fracture (in descending order) in mandible are the body, angle, condylar region, symphysis, and coronoid process.\textsuperscript{8}

Treatment of mandible fractures has changed over the last 20 years. There has been a decrease in the use of wire osteosynthesis and intermaxillary fixation and an increase in preference for open reduction and internal fixation with miniplates.\textsuperscript{9} This has helped to reduce malocclusion, non-union, improved mouth opening, speech, oral hygiene, decrease loss and the ability for patients to return to work earlier.\textsuperscript{9}

The aim of the study was to see the epidemiology & clinical profile of mandible fracture and different methods of mandible fractures management. A clearer understanding of pattern of mandible fractures will assist health care providers as they plan and manage the treatment of traumatic maxillofacial injuries. Such information can also be used to guide the future funding of public health programmer geared toward prevention.\textsuperscript{8}

\textbf{Methodology:}

Descriptive type of retrospective cross sectional study was conducted in the casualty department of Oral and Maxillofacial Surgery of Dhaka Dental College & Hospital during the year of January 2014-December 2015. The Department of Oral and Maxillofacial Surgery of Dhaka Dental College is the largest centre for facial trauma management in Bangladesh. Among four hundred and thirty five patients with mandible fractures who managed in this department during the year 2014-2015. Epidemiological & Clinical information were extracted from the case records form which included gender, age, etiology of injury, area of injuries and treatment methods. The mechanism of injury was recorded as Road traffic accident, Physical assault, fall, Sports injury, Blow by heavy objects, Tube well injury & others. Site of fractures was recorded and methods of management were included.

Data was collected and tabulated by using Microsoft Excel 2007.

\textbf{Results:}

In the studied period, mandible fractures were diagnosed in 435 patient’s data regarding age, gender, cause of fracture, anatomic site and treatment modalities were reviewed. There was higher prevalence in male (3.9:1). (Figure-1)

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{fig1.png}
\caption{Gender distribution of the respondents (n=435)}
\end{figure}

Figure illustrates the sex distribution of the respondents. Out of 435 patients 345 (79\%) were male and 90 (21\%) were female respondents. Male were predominant.

Age incidence was peak between 21-30 years. (Figure-2)

\begin{table}[h]

Figure shows treatment modalities for mandible fractures.

Discussion:

All over the world, maxillo-facial injuries have continued to generate discussion among researchers, due to the functional and cosmetic deformities affecting the victims. The etiological factors and pattern of maxillo-facial injuries have been reported to vary from one geographical area to another, depending on the socioeconomic status, geographic condition and cultural characteristics. Despite the fact that it is the heaviest and strongest facial bone, the mandible is prone to fractures for some specific reason: 1) it is an open arch; 2) it is located in the lower portion of the face; 3) it is the mechanism of hyperextension and hyperflexion of the head in traffic accidents; 4) it gets atrophy as a result of aging.

The results of this study of mandible fracture coincide with previous reports, particularly regarding age and sex of patients. In our study, the highest incidence of mandible fractures is found in the age group of 21–30 years (26.89%). Age incidence was similar with a study by Amin et al. The possible reasons for this in our geographic area may be very high use of two-wheelers, early bikers, lack of safety measures in the form of...
helmets and improper road conditions, as most of
fractures in this group belong to RTAs.\(^2\)
There was higher prevalence in male (3.9:1). The male
predominance observed in our study agrees with data
reported in literature around the world, namely a male-
to-female ratio of approximately 3:1.\(^1\) Males are more
exposed, due to their more frequent participation in
high risk activities, such as driving vehicles, sports that
involve physical contact, an active social life, drugs
and alcohol habits, etc.\(^10\)
The principal causes of fracture in this study were RTA
(Road Traffic Accidents) representing 54.02 \%(n=235), followed by Physical assault 17.24 \%(n=75),
Fall, Sports injury, Blow by heavy objects, Tube well
injury & others. There is a stark difference in the
etiology of maxillofacial trauma in developing and
developed nations. The common cause of maxillofacial
trauma in developing countries is RTAs, while assault
is the most common cause in developed countries. Our
findings also support the same, as 68\% of our patients;
RTA was the cause of injury.\(^2\) These etiological
differences reflect differences in the socioeconomic factors, national infrastructure development
(particularly roadways, traffic regulations and legislation) and other behavioral habits, such as alcohol
consumption or criminal activities. The high number
of maxillo-facial injuries attributed to RTA is explained by inadequate road safety awareness; unsuitable road conditions.\(^2\)
The most common site of fracture in mandible
evidenced by the present investigation was the
paramedian one (26.31\%), which is consistent with the
findings of King\(^12\), who established a statistical
significance between road traffic accidents and
parasymphysis fractures. Atanasov\(^13\) and Wong\(^14\)
reported that motorcycle accidents (79.5\%) were the
major cause of mandible fractures, with the
parasymphysis as the most common site. Sunita Malik
et al.\(^15\) also founded parasymphysis as the most
common site of fracture in the mandible. hout
expansion of motorworks; violation of speed limit; old
vehicles without safety features\(^12\)
In present study angle of mandible fractures were
second most common 17.89\%. However, Olson et al.\(^16\)
showed that there was a higher incidence of angle
involvement in patients with mandible trauma.\(^5\)
However, our study was not consistent with the findings
of Adekeye\(^17\), Nair\(^18\) and Adebayo\(^19\), who reported
the body as the most prominent site, whereas Van Beek
\(^20\) found the condyle as the most common site.\(^11\) It is
difficult to cite a reason for this difference; perhaps
further study on the causes of the regional mandible
fractures would be useful. One can speculate that inter-
population difference in the sites of mandible fractures
partly related to the diverse etiologic factors involved.\(^8\)
Several treatments may be applied in maxillofacial
fractures, the differences among them depending on
many factors, such as costs, patient’s affordability,
conditions in the hospital, doctor’s decision and skill,
patient’s willingness to obey the treatment - all of them
varying from one country to another. The choice of
either closed or open approach methods of treatment
of mandible fractures depended mainly on availability
of resources\(^21\). Due to absence of facilities of GA at
causality department, most of the patients70.11%
treated from closed reduction with arch bar fixation,
and only few of them had open reduction and internal
fixation, which is consistent with the studies conducted
by Kamulegeya A.\(^22\), Chandra\(^23\), Erol et al.\(^24\), Kilasara
et al.\(^25\) and Sunita Malik et al.\(^15\). Open reduction and
internal fixation has been reported to be the “gold
standard” of the treatment of maxillo-facial fractures\(^11\).
In recent years, there has been a trend towards rigid
fixation with miniplates. In our study 22 cases
(21.83\%) were treated with miniplates. The
postoperative results were satisfactory. Most of the
patients belong to low socio-economic status;
therefore, limited numbers of cases were selected for
miniplate fixation.

Conclusions:
Road traffic accidents (RTA) represented the major
etiological factor of maxillo-facial injuries, with young
adult males as they are main victims. The high number
of trauma victims with maxillofacial injuries evidenced
in the present study highlights the importance of the
Dental Surgery unit, besides the other disciplines
assuring an emergency management of trauma victims.
This study also evidences the importance of cooperation and coordination among the various
medical disciplines, for a rapid management of
maxillo-facial injuries, and not only, which might
prevent functional as well as aesthetic morbidity.
