Abstract
Treatment of \([\text{Re}_2(\text{CO})_{10}(\text{MeCN})_2]\) with 2-(methylmercapto)benzothiazole/2-(methylmercapto)benzimidazole in refluxing benzene resulted in the isolation of compounds \([\text{Re}_2(\text{CO})_8(\mu-\eta^1,\eta^1-(\text{C}_7\text{H}_4\text{NS})\text{SCH}_3)]\) and \([\text{Re}_2(\text{CO})_8(\mu-\eta^1,\eta^1-(\text{C}_7\text{H}_5\text{N}_2)\text{SCH}_3)]\) in moderate yield. The compounds have been characterized by IR, \(^1\text{H}\) NMR, \(^1\text{C}\) NMR and mass spectral data.

Introduction
Nitrogen and sulfur containing heterocycles represent an important class of ligands in organometallic chemistry. Such ligands offer new possibilities for the preparation of bimetallic complexes with potential application in catalysis. Binuclear complexes bridged by multidentate ligands have been the subject of considerable amount of work in the last two decades. Rhenium complexes of general formula \([\text{[(µ-H)Re}_2(µ-Y)(\text{CO})_8]]\) (Y = PR\(^3\), Cl, I, \(\eta^2\)-pyridyl, \(\eta^2\)-C≡CR, \(\eta^2\)-C=CRR, C(R)O, SR) are well known in recent organometallic chemistry papers. Considerable interest in this area and the reactivity of N and S containing heterocycles with transition metal carbonyls have grown because of the presence of more than one type of donor atoms in these ligands that can introduce novel reactivity and frequently stabilizes the metal cluster framework by acting as bridging or chelating ligands.

Over the last few years Kabir et al. have been investigating the oxidative addition reactions of a series of N and S containing heterocycles such as benzothiazole, thiomorpholine, thiazolidine, 4-methyle thiazole, and thiazole with ruthenium and osmium carbonyls and observed a remarkable influence on the type of the products obtained depending on the carbonyls, the heterocyclic ligands as well as the reaction conditions.

For example, thiomorpholine C\(_2\)H\(_5\)NS reacts with [Ru\(_3\)(CO)]\(_{12}\) at 66°C to give [Ru\(_3\)(µ-\(\eta^2\)-SCH\(_2\)CH\(_2\)NH\(_2\))(CO)\(_6\)] by a ring opening reaction of the ligand followed by the elimination of a C\(_2\) fragment whereas under identical conditions thiazolidine,C\(_2\)H\(_5\)NS, forms the dinuclear compound [Ru\(_3\)(µ-\(\eta^2\)-SCH\(_2\)CH\(_2\)NHCH\(_2\)) (CO)\(_8\)] followed by ring opening cleavage of the ligand as well as the rapture of the metal-metal bonds. (Scheme-1).
The reaction of the labile cluster \([\text{Os}_3(\text{CO})_{10}(\text{MeCN})_2]\) with thiazole gives two isomeric products, \([(\mu-\text{H})\text{Os}_3(\text{CO})_{10}(\mu-2,3-\eta^2-C=\text{N-CH=CHS})] 2.1\) and \([(\mu-\text{H})\text{Os}_3(\text{CO})_{10}(\mu-3,4-\eta^2-\text{CH=NC=CHS})] 2.2\) in 20\% and 60\% respectively as shown in (Scheme-2) by ortho C-H activation with respect to N atom.

Treatment of \([\text{Re}_2(\text{CO})_6(\text{NCMe})_2]\) with five equivalents of thiazole and 4-methylthiazole in refluxing benzene gave two new sets of compounds \([(\mu-\text{H})\text{Re}_2(\text{CO})_7(\mu-2,3-\eta^2-\text{C}_3\text{H}(4-\text{R})\text{NS})\{\eta^1-\text{NC}_3\text{H}_2(4-\text{R})\text{S}\}] (3.1, \text{R= H}, 3.2, \text{R=CH}_3)\), \([(\mu-\text{H})\text{Re}_2(\text{CO})_6(\mu-2,3-\eta^2-\text{C}_3\text{H}(4-\text{R})\text{NS})\{\eta^1-\text{NC}_3\text{H}_2(4-\text{R})\text{S}\}] (3.3, \text{R= H}, 3.4, \text{R=CH}_3)\) and \(\text{fac-}[\text{Re}(\text{CO})_3(\text{Cl})\{\eta^1-\text{NC}_3\text{H}_2(4-\text{R})\text{S}\}]_2\) \(3.5, \text{R= H}, 3.6, \text{R=CH}_3\) (Scheme-3).
Recently Azam et al. reported the reaction of \([\text{Os}_3(\text{CO})_{10}(\text{NCMe})_2]\) with 4-methylthiazole and afforded a decacarbonyl compound \([\mu-\text{H}]\text{Os}_3(\text{CO})_{10}(\mu-2,3-\eta^2-\text{C}=\text{N-Me}=\text{CHS})\) \(4\) (Scheme 4) in a moderately high yield.\(^{15}\)
Studies on the interaction of rhenium carbonyls with both nitrogen and sulfur containing heterocycles are not well studied. Keeping these ideas in mind and as a continuation of our previous works on rhenium carbonyl chemistry we have decided to investigate the reaction of \( \text{Re}_2(\text{CO})_8(\text{NCMe})_2 \) with 2-(methylmercapto)-benzothiazole / 2-(methylmercapto)benzimidazole ligands.

**Results and Discussion**

**Reaction of \( \text{Re}_2(\text{CO})_8(\text{NCMe})_2 \) with 2-(methylmercapto)benzothiazole / 2-methylmercapto-benzimidazole**

The reaction of \( \text{Re}_2(\text{CO})_8(\text{NCMe})_2 \) with ligand \( \text{L} = (2\text{-}(\text{methylmercapto})\text{ benzothiazole/2-methylmercapto-benzimidazole}) \) in 1:2 molar ratio in refluxing benzene for 4 hours afforded the compound \( \text{Re}_2(\text{CO})_8(\mu-\eta^1,\eta^1-(\text{C}_7\text{H}_5\text{NS})\text{SCH}_3) \) 5a and \( \text{Re}_2(\text{CO})_8(\mu-\eta^1,\eta^1-(\text{C}_7\text{H}_6\text{N}_2)\text{SCH}_3) \) 5b respectively. (Scheme 5) as orange crystals in 28-30% yield. The compound has been characterized by IR, \(^1\text{H} \text{NMR} \) and mass spectral data.

![Scheme 5](image-url)
A plausible mechanism for the formation of the compound

The compounds are believed to be formed simply by the displacement of the two acetonitrile ligands from $[\text{Re}_2(\text{CO})_8(\text{NCMe})_2]$ which may occur in two general pathways (Scheme-6). One path A begins with the formation of Re-N bond by the substitution of an acetonitrile molecule. Pathway B involves initial coordination of 2-(methylmercapto)benzothiazole ligand through sulfur to Re atom by the displacement of...
an acetonitrile molecule. It may be assumed that the first step in pathway A occurs more rapidly than the first step in pathway B because of the small SMe group in 1 compared to the bulky benzothiazolyl group in II. However, our attempt of isolating such intermediates were unsuccessful for the rapid displacement of the second acetonitrile molecule. Moreover the N of the heterocycles gets preference than the sulfur due to rapid C-S bond rotation at such higher temperature.

**Spectroscopic characterization of \([\text{Re}_2(\text{CO})_8\{\mu-\eta^1,\eta^1-(\text{C}_7\text{H}_4\text{NS})\text{SCH}_3\}]\)5a and \([\text{Re}_2(\text{CO})_8\{\mu-\eta^1,\eta^1-(\text{C}_7\text{H}_5\text{N}_2)\text{SCH}_3\}]\)5b**

The compound 5a shows νCO absorption bands in KBr at 2074s, 2023s, 1938m and 1889m cm\(^{-1}\). These are the characteristics of a typical dinuclear metal carbonyls. The \(^1\)H NMR spectrum of the compound 5a in CDCl\(_3\) shows signals at δ 3.18 (s, 3H), 7.50 (ddd, 1H, (H\(_2\) or H\(_3\)) \(J=8.0\) Hz), 7.77 (ddd, 1H, (H\(_2\) or H\(_3\)), \(J=8.0, 6.0, 1.0\) Hz), 7.83 (dd, 1H, H\(_a\), \(J=8.0\) Hz), 8.26 (dd, 1H, H\(_1\), \(J=8.0\) Hz).

The mass spectrum of compound 5a shows the parent molecular ion peak at m/z 777. Other important peaks at m/z 762 (M\(^+\) - CH\(_3\)), 678 (M\(^+\) - CH\(_3\)-3CO), 553 (M\(^+\) - 8CO), 452 (M\(^+\) - Re–5CO) are observed.

The compound \([\text{Re}_2(\text{CO})_8\{\mu-\eta^1,\eta^1-(\text{C}_7\text{H}_5\text{N}_2)\text{SCH}_3\}]\)5b shows νCO absorption bands in KBr at 2090s, 2030s, 1920m and 1850m cm\(^{-1}\). These are the characteristics of a typical dinuclear metal carbonyls. The \(^1\)H NMR spectrum of the compound 5b in CDCl\(_3\) shows signals at δ 3.05 (s, 3H), 7.76 (ddd, 1H, (H\(_2\) or H\(_3\)) \(J=8.0\) Hz), 7.44 (ddd, 1H, (H\(_2\) or H\(_3\)), \(J=8.0, 6.0, 1.0\) Hz), 7.33 (dd, 1H, H\(_a\), \(J=8.0\) Hz), 8.14 (dd, 1H, H\(_1\), \(J=8.0\) Hz). 12.2 (s, broad, 1H, NH).

\(^13\)C NMR spectrum of 5b in CDCl\(_3\) shows signals at δ 34.24, 77.52, 111.7, 120.7, 125.7, 125.9, 133, 144.3, 165.19, 190.39, 195, 204.54 ppm. The signal at δ 34.24 is due to the -CH\(_3\) carbon (C\(_a\)). The signal at δ 77.52 is due to the CDCl\(_3\) (Solvent). The signals at δ 111.7, 120.7, 125.7, 125.9, 133, 144.3, are due to the benzene ring carbons (C\(_c\), C\(_b\), C\(_e\), C\(_f\), C\(_g\), C\(_h\)). The signal at δ 165 is due to the C\(_b\) carbon atom which lie between two N atoms. The signals at δ 190.39, 195 and 204.54 are due to the carbonyl carbon atom.

The mass spectrum of compound 5b shows the parent molecular ion peak at m/z 760. Other important peaks at m/z 745 (M\(^+\) - CH\(_3\)), 660 (M\(^+\) - (CH\(_3\)+3CO), 619 (M\(^+\) - 5CO), 535 (M\(^+\) - 8CO) and 164 base peak which corresponds to the ligand.

The exact bonding mode of the ligand could not be ascertained without the X-ray crystal structure determination. It is proposed from the IR, NMR and Mass spectral data that the molecules consist of a diphosphorus core with eight terminal carbonyl ligands and a four electron donor 2-(methylmercapto)benzothiazole and 2-(methylmercapto)benzimidazole
ligand respectively. An interesting structural feature of the compound is the coordination of the ligand L (2-(methylmercapto)benzothiazole and 2-(methylmercapto)benzimidazole) in a $\mu$-$\eta^1$, $\eta^1$- fashion to one Re atom through the nitrogen and other Re atom through the sulfur atom. Each rhenium atom attains a slightly distorted octahedral arrangement through the terminal carbonyl ligands and the organic moiety. The molecule is electron precise with one metal-metal bond and obeys the 18 electron rule.

**Experimental**

**General remarks**

All the reactions were carried out under a dry nitrogen atmosphere using standard Schlenk techniques. Solvents were purified and distilled from the appropriate drying agents and stored under nitrogen prior to use. Products were separated by thin layer chromatography (TLC) on silica gel (type-60) GF$_{254}$ Merck 7730 in air. Infrared spectra were recorded on a Shimadzu FTIR 8101 spectrophotometer. $^1$H NMR and $^{13}$C NMR spectra were recorded on a Bruker DPX 400 spectrometer. The chemical shifts were referenced to the residual solvent proton resonances ($\delta=7.24$ ppm for CHCl$_3$). Mass spectra were recorded on a varian MATC7H instrument (direct injection, electron impact ionization 70ev). The compound [Re$_2$(CO)$_8$(MeCN)$_2$] was prepared according to the known procedure. 2-(methylmercapto)benzothiazole and 2-(methylmercapto)benzimidazole were purchased from Adrich chemical company and used as received.

**Preparation of [Re$_2$(CO)$_8$(MeCN)$_2$]**

A three necked round bottom flask equipped with a pressure-equalizing dropping funnel was flushed with nitrogen and charged with [Re$_2$(CO)$_{10}$] (1.0g, 1.5 mmol), CH$_2$Cl$_2$ (10 cm$^3$) and MeCN (10 cm$^3$), Me$_3$NO (0.23g, 3.0 mmol) in CH$_2$Cl$_2$ (5 cm$^3$) was added drop wise over 1h and the reaction mixture stirred at room temperature until complete conversion was occurred (22-24h, monitored by analytical TLC). Evaporation of the solvent and recrystallization from CH$_2$Cl$_2$/hexane containing a few drop of MeCN gave pure [Re$_2$(CO)$_8$(MeCN)$_2$] (0.08g,80$\%$) as yellow crystals.$^{18}$

**Reaction of [Re(CO)$_8$(MeCN)$_2$] with ligand L (L= 2-(methylmercapto)-benzothiazole / 2-(methylmercapto)-benzimidazole**

A dry nitrogen flushed 100 ml three-necked flask was equipped with a magnetic bar, thermometer, rubber septum and a reflux condenser. A solution of [Re$_2$(CO)$_{10}$(MeCN)$_2$] (0.02g, 0.29 mmol), and ligand L (0.59mmol) in freshly distilled benzene (30 cm$^3$), was heated to 80$^\circ$C in an oil bath and refluxed for 4 hours with continuous stirring. The colour of the reaction mixture changed from yellow to orange. The solvent was removed under vacuum and the residue separated by TLC [SiO$_2$; eluant: cyclohexane-
dichloromethane (7:3,v/v)] to give the compounds [Re₂(CO)₈(µ-η¹,η¹-(C₇H₄NS)SCH₃)]
5a (0.056g, 28%) as orange and [Re₂(CO)₈(µ-η¹,η¹-(C₇H₅N₂)SCH₃)] 5b (0.067g, 30%)
as lemon yellow crystals from n-hexane / CH₂Cl₂ mixture at room temperature.
