Abstract:

Background: Induced hypotension is used to reduce blood loss especially in those operations where even a small amount of blood can obscure the operative field such as spine surgery.

Objectives: To compare the effect of labetalol with that of glyceryl trinitrate to reduce intraoperative blood loss by inducing elective hypotension without any tachycardia and to improve quality of surgical field during spine surgery.

Method: A total number of thirty patients (ASA grade I & II) were selected randomly into two groups, fifteen in each group. Group-I received glyceryl trinitrate (1000µg) and Group-II received labetalol (5mg) intravenously 3 minutes before induction of anaesthesia. Heart rate, mean arterial pressure was observed in two study groups 15 minutes interval in intra-operative period and quality of surgical field was detected by 4 points VRS (Verbal rating scale) after completion of surgery by asking the surgeon.

Results: Heart rate varied significantly in two study groups after induction of anaesthesia except baseline and pre induction (p< 0.05). Labetalol associated with improved quality of surgical field visualization than glyceryltrinitrate (p = 0.034).

Conclusion: Our study concluded that labetalol is effective than glyceryltrinitrate to reduce blood loss in spine surgery.

Key words: spine surgery, labetalol, glyceryltrinitrate, intraoperative period, quality of surgical field, mean arterial pressure, verbal rating scale.

Introduction:

Anaesthesia may influence intraoperative bleeding in several ways both physiologically and pharmacologically. Elective hypotension is used to reduce operative blood loss especially in those operations like spine surgery, middle ear surgery, cerebro-vascular surgery where even a small quantity of blood can obscure the operative field and make difficulties for the surgeon for a good proper surgery and prolong duration of operation. Laryngoscopic stimulation of oropharyngeal structure may be an important factor in the haemodynamic stress response associated with tracheal intubation. Instrumentation of pharynx and tracheal intubation may result in tachycardia, hypertension and increased plasma catecholamine concentration that may evoke life threatening condition among susceptible individuals especially those with cardiovascular disease. Hypotensive anaesthesia has long been established as safe as effective method for reducing blood loss upto 80%.

Various types of pharmacological agents used to achieve hypotensive anaesthesia have been studied during spine surgery. They include ganglion blocking agents, volatile agent. Calcium channel blocker, sodium nitroprusside.
nitroglycerine, α & β adrenergic blocker. Mean arterial pressure (MAP) is typically maintained at 60-70 mmHg. These drugs, however, are not entirely satisfactory, as tachyphylaxis and undesirable tachycardia often occur. There is little evidence that any particular agent is superior but the avoidance of tachycardia is an essential part of a good anaesthetic technique.

Labaetalol is both α & β adrenergic receptor blocker which reduces blood pressure without significant altering either resting heart rate or cardiac output. Glyceryl trinitrate alternative relaxes vascular smooth muscle with venous dilatation predominating over arterial dilatation reduces blood pressure by reducing preload but it causes reflex tachycardia.

In our present study we compare the effects of labetalol with that of glyceryltrinitrate for safe elective hypotensive anaesthesia to reduce the blood loss so as to produce a clear surgical field during intraoperative period of spine surgery.

Methods

Study population:
Total 30 patients of type of spinal pathology scheduled for spinal surgery was recruited for the study. University departmental ethics committee give consent before carrying out the study. Informed consent were taken from all patients before the procedure.

After recruitment, thirty patients of both sex, male and female aged 15-60 years, ASA grade I and II divided in two groups. Fifteen patients in each group. Patients were randomly divided into two groups. According to card number, patients grouped. Patients with history of bronchospasm, significant ventricular hypertrophy, Sinus bradycardia (< 45-50 beats/min), allergic rhinitis, 2nd and 3rd degree heart block, congestive heart failure, diabetes mellitus were excluded from this study.

Patients data were collected from pre anaesthetic assessment audit form. Preoperative parameters (pulse rate, systolic and diastolic blood pressure, mean arterial pressure, SpO₂) were recorded. Intravenous canula inserted on left hand. After recording pulse, blood pressure, SpO₂, Group-I received glyceryl trinitrate (1000µg) and Group-II was received inj. Labetalol (5mg) intravenously 3 minutes before induction of anaesthesia.

Pre-oxygenation was done for 3-5 minutes with 100% oxygen, induction of anaesthesia was done with fentanyl (1µg/kg) and thiopentone sodium (5mg/kg) and endotracheal intubation was done by suxamethonium (1.5mg/kg). Maintenance of anaesthesia with N₂O 70%, O₂ 30% and halothane (0.5% -1%) with non depolarizing neuromuscular blocking agent vecuronium bromide (0.1mg/kg) incremental dose of fentanyl (0.3 – 0.4µg/kg) was given as needed. Intraoperative fluid was maintained with Hartmann’s solution or normal saline. Intraoperatively 15 minutes interval pulse rate, systolic and diastolic blood pressure and mean arterial pressure observed. Mean arterial pressure was maintained at 70-80 mmHg. Quality of surgical field was observed by points VRS (Verbal rating scale) (1. Not satisfactory 2. Moderate satisfactory, 3. Good, 4. Excellent) and detected by asking the surgeon after completion of surgery. In Group-I glyceryl trinitrate (1000µgm) given at 15 minutes interval and also given as required to maintain desired mean arterial pressure and in Group- II. labetalol (5mg) given at 30 minutes interval also given as required. Operation time was on average about two hours.

Statistical Analysis:
All the variables were expressed as mean ± SD. Student t-test and chi-square (χ²) test were done as the tests of significance where applicable to compare the mean of different groups. The statistical analysis was done by using SPSS programme. P value < 0.05 was considered as significant.

Results:
Observation of the present study was analyzed in the light of comparison among each subject groups. Each group having n=15. All results were expressed as mean ±SE or in frequencies as applicable. The groups became statistically matched for age (p=0.366), weight (p=0.697), sex (p=.705). ASA grading (p=0.713). There was no significant difference among the study groups.
Baseline mean heart rate in Group-I was 81.80±2.219 and in Group-II was 82.13±1.633, where, p= 0.905 (Table-II).

Pre-induction mean heart rate in Group-I was 85.60±2.276 and in Group-II 83.07±2.525, where p=0.462.

Heart rate of two studied groups are displayed, where baseline and pre-induction values were not significantly difference in two groups.

Heart rate varied significantly at 15min (p=0.027), 30 min (p= 0.009), 45 min (p= 0.024), 60 min (p= 0.002), 75 min (p= 0.015), 90 min (p= 0.001) after induction of anaesthesia.

Heart rate of two study groups displayed in Fig: 1

Values are expressed as mean ±SD. Data are analyzed by student t test, values are regarded as significant P<0.05. ns = non significant, s =significant

Regarding heart rate there is slight increase in heart rate in group I. There was significant change in Fig.-1.
Baseline mean arterial pressure in Group I was 101.00±2.951 and in Group II was 98.27±3.591 where p = 0.552 (Table-III).

Pre-induction mean arterial pressure in Group-I was 97.00±2.908 and in Group-II 93.40±3.634 where p = 0.446.

Mean arterial pressure of two studied groups are displayed, where baseline and pre-induction values were not significantly different in two groups, but varied significantly at 15 min (p = 0.006), 30 min (p = 0.024), 60 min (p = 0.042) after induction of anaesthesia.

Mean arterial pressure of study groups is displayed in Fig: II.

Data analyzed by chi-square (χ²) test, value are regarded as significant (P <0.05).

Improved quality of surgical field visualization was detected after completion of surgery by asking the surgeon by verbal rating scale (VRS). “Bleeding obscure surgical field” group I =3, group II= 0. Moderate
bleeding obscure surgical field group I = 8, group II= 4, Mild bleeding but surgical field is clear group I = 4, group II= 8, Excellent surgical field group I = 0, group II= 3 (Table-IV).

Group-II associated with significant improved quality of surgical field (p=0.034).

Discussion:
Elective hypotension is a specific anaesthetic technique which goes beyond the ability of a good, safe, non-stress-inducing anaesthetic to reduce blood loss. Its use may be classified broadly as applicable to situations in which the particular operation would otherwise be impossible (for example cardiovascular or cerebrovascular surgery). Situations in which excessive blood loss might be detrimental (for example orthopaedics, spinal, and maxillo-facial operations) and situations in which blood loss interferes with surgical visibility or technique (such as middle ear surgery and spine surgery).

Bloodless surgical field helps the surgeon to operation in short time and without damage of any important nerve roots due to clear visible surgical field.

The benefits of induced hypotension during spine surgery include reduction in blood loss and also reduce need for blood transfusion, improved quality of surgical field and shorter duration of surgery. A number of hypotensive agents have been studied include ganglion blocking agents, volatile agents, calcium channel blocker, sodium nitroprusside, nitroglycerine, α-blocker. These drugs however are not entirely satisfactory as tachyphylaxis or undesirable tachydardia often occur.

Labetalol has stereoisomers. It is a racemic mixture of four isomers. Two of these isomers, the (S,S)- and (R,S)-forms are inactive. The third, the (S, R)-isomer, is a powerful α₁ blocker. The fourth isomer, the (R, R)-isomer, is a mixed nonselective β blocker and selective β₂ antagonist.

It works by blocking these adrenergic receptors, which decreases peripheral vascular resistance without significantly altering heart rate or cardiac output. The α:β antagonism of Labetalol is approximately 3:1. Glyceryl causes venous dilatation predominating over arterial dilatation reduced blood pressure by reducing preload but it causes reflex tachycardia.

Kadam PP studied hypotensive anaesthesia for spine surgery comparing nitroglycerine vs halothane. In this prospective study 30 patients (ASA I or II) requiring spine surgery under general anaesthesia were studied. Group-I received halothane 0.5-2.5% and group- II received intravenous nitroglycerine infusion 1-2 µg/kg/min. They studied blood pressure, blood loss, operating time and recovery score. In their study there was no significant between groups differences in patients demographic data. There was no significant difference in haemodynamic parameters. The blood loss with nitroglycerine was significantly less (202±114ml) than halothane groups (602±312 ml). All the patients were alert at the end of surgery in nitroglycerine groups (recovery score 9.8± 0.76) as against the halothane groups (7.98±0.9) (p< 0.01).

By comparing with this study, in our study we found there were no significant difference between groups in patients demographic data and less blood loss in Labetalol group. Kaplan et al did not observe significant change in heart rate when nitroglycerine was used to control blood pressure during coronary artery surgery. They suggested that gradual reduction in blood pressure by nitroglycerine prevented an increase in heart rate. But in our study heart rate varied significantly at 15 min (p =0.027), 30 min (p =0.009), 45 min (p =0.024), 60 min (p =0.002), 75 min (p =0.015), 90 min (p =0.001) after induction of anaesthesia except base line and pre induction.

There was no significant difference in mean arterial pressure between groups except 15 min (p=0.006), 30 min (p=0.024), 60 min (p=0.042), after induction of anaesthesia.

Also in our study labetalol was associated with improved quality of surgical field than glyceryltriminate 10%, 0% respectively (p=0.034).

In our study, 1 patient in labetalol group, 2 patients in glyceryltriminate required blood transfusion. So from above observation we found that heart rate remains stable in labetalol group than glyceryltriminate intraoperatively. Mean arterial pressure was maintained at 70-80 mm of Hg in labetalol group. Dose requirement and time interval decrease in labetalol group and also decrease the requirement of blood transfusion.

So our result showed that labetalol (5mg) administered intravenously 3 minutes before...
induction of anaesthesia is effective than glyceryltrinitrate to reduce blood loss intraoperatively and improved quality of surgical field in spine surgery.

**Conclusion:**
Under the condition of present study, it was found that intravenous labetalol is a more safe hypotensive agent in comparison to glyceryltrinitrate in spine surgery.
