Abstract

Background Day care surgery is widely acceptable and gaining popularity for more than a decade. Early recovery and cost effectiveness is an integral part of day care surgery in developing country.

Objective To compare the cost effectiveness & recovery score after oral midazolam and thiopental sodium or propofol induction in day care surgery.

Methods A total number of sixty patients, thirty in each group of ASA grade I & II were selected. In group -A patient receiving propofol 2mg/kg for induction and group B were given oral midazolam 0.25mg/kg thirty minutes before induction with thiopental sodium 2.5mg/kg. Perioperative heart rate, BP, recovery score and time to ready to go home were monitored. Average cost of induction was calculated in both groups.

Result Recovery scores in group A & B were 8.8 ±1.75 and 8.01 ±1.03 respectively after thirty minutes of reversal. The cost of group B (BDT 37.88±1.37) was significantly lower (P<0.05) than that of group A (BDT 142.00 ± 6.00).

Conclusion Preoperative oral midazolam & low dose thiopental sodium induction is relatively cost effective than propofol induction in day care surgery.

Key word: Day care surgery, Oral midazolam, thiopental sodium, propofol.

Introduction

Surgical day-cases are admitted for operations or investigations on a planned, non-resident basis and occupy beds for a period of time in a unit set aside the operation theatre complex and go back home on the same day, also called 'out-patient ambulatory surgical cases'. It is one of the most dramatic transformations in health care delivery in the recent past. The primary impetus for this change is the economic saving afforded by not admitting patients the night before surgery or keeping them in hospital over night after surgery. Other advantages include earlier ambulation, patients’ convenience and a lessened risk of nosocomial infections.

Prerequisites for this are agents having characteristics of rapid efficient action with quick elimination without hang-over effect and of course cost effective. None of the currently available anaesthetic agents have duration of action short enough to leave the patient with no residual effects within a few hours of surgery. Commonly used induction agent, Thiopentone is having elimination half-life of 5 to 10 hours and up to 30% may remain in the body after 24 hours. It does not provide a clear-headed recovery in day-case anaesthesia. On the other hand, Propofol has distribution and elimination half-lives of 1 to 2 minutes and 1 to 5 hours respectively and provides rapid recovery
with minimal residual effect which is suitable for
day-cases\textsuperscript{4}. But high price of Propofol and also
change of contamination of vials are major
hindrance to its use for day-cases in the
underprivileged population\textsuperscript{2,4}.

Midazolam is a potent sedative, adjuvant to
hypnotics, with a flat cardio-vascular profile,
readily absorbable with an onset of effects within
10 to 15 minutes after oral administration\textsuperscript{5}. Even
at 30 mg oral dose does not accumulate in plasma
(<2ng/ml) with less chance of any adverse effects
and prolonged action, thereby renders a quick and
clear-headed recovery\textsuperscript{6}.

This study was carried out to compare the quality
of recovery from Propofol induction with
thiopentone along with oral midazolam. The cost
effectiveness of these induction agents were also
evaluated to observe the benefit of the patient.

Methods
This study was conducted in Department of
Anaesthesia, Analgesia and Intensive Care
Medicine, BSMMU, Dhaka from July to September
2005. Sixty gynaecological patients within 18 to 35
years of age, belonging to ASA (American Society
of Anaesthesiologists) status I and II, scheduled
for routine laparoscopic procedure on day-case
basis. Patients were randomly selected by card
sampling method and grouped equally into two with
thirty in each group. After pre-oxygenation, Group-
A received propofol 2 mg/kg for induction and
Group-B were given midazolam 0.25 mg/kg orally
30 minutes before induction by thiopentone 2.5
mg/kg. Medium-acting vecuronium was used for
endotracheal intubation and muscle relaxation.
Analgesia and maintenance were managed by
fentanyl 1mgm/kg and 0.5% halothane respectively.
Per-operative vital parameters were observed and
recorded at 5 min interval. Recovery quality was
assessed by SOCA (S-Sedation, O-Orientation, C-
Comprehension, and A-Amnesia) scores and time
required for fitness to go home were monitored &
recorded. After completion of surgery, total cost
of induction agents was calculated and recorded.

Data were collected in a pre-design ‘data collection
sheet’. Data were compiled and statistical analysis
were done using student’s ‘t’ test with the help of
SPSS version 11. Values are regarded as significant
if p <0.05.

* 10 out of 11 must be scored before discharge under normal circumstances.

Fitness to go home\textsuperscript{8}
1) Orientation to person, place and time.
2) Stable vital signs for 30-60 minutes.
3) Ability to ambulate unassisted.
4) Ability to tolerate oral fluids.
5) Ability to void.
6) Absence of significant pain or bleeding.

Results:
Patient’s characteristics are shown in table-I and
there were no significant differences among both
groups.

Patient’s vital parameters like heart rate, systolic
and diastolic blood pressure were recorded at
various timing. There was not much variation
regarding those vital parameters among both
groups (Table II and Figure 1).

Recovery score at different timing is shown in
Table-III. Immediately after reversal recovery
score for group A and group B were 5.98±2.00
and 5.26±1.84 respectively. Score were recorded
after 5, 10, 15, 20, 25 and 30 minutes of reversal.
Thirty minutes after reversal this score was
8.86±1.75 and 8.01±1.03 for group A and group B
respectively.
Time for fitness to go home was recorded when
patients were fulfilled the criteria for fitness to go
home. It was 281±44 and 321±53 minutes for group
A and group B respectively (Table-IV).
Cost of induction agents was relatively higher in
group A (142.00±6.00) than that of in group B
(37.88±1.37) [Table-V].

Discussion
Proper selection, planning & uneventful clear-headed anaesthetic recovery are the hallmarks of fruitful day-case surgery. Many operations are performed at one-fifth cost of inpatient surgery if carried out on a day-case basis$^9$. These are economical when they come-out safely with an early discharge. This study was to find-out a cost-effective recipe of induction agent, alternative to propofol which is the choice in day-cases but quite expensive. Co-induction with oral midazolam (0.25 mg/kg) and a reduced dose (2.5 mg/kg) of conventional intravenous thiopentone revealed the recovery status nearly closed to that of propofol. The variation in recovery scores (Table-III) and time for fitness to go home (Table-IV) between the two groups were almost similar. Moreover, the peri-operative parameters like heart rate, systolic and diastolic blood pressure (Table-II and Figure-1) deviations between the groups were also similar.

One study showed that after receiving 10 mg of i.v. midazolam the recovery in relation to orientation of time and place occurs within 15 minutes. Pharmacokinetics of midazolam after both i.v. and oral administration to healthy volunteers are broadly similar$^{10}$. When patients are induced with thiopentone, awakening ranges from 1½ to 2½ times prolonged with midazolam$^{11}$. So, to avoid that delay, a reduced dose of thiopentone was used and supplemented with low-dose volatile to maintain adequate depth of anaesthesia. The addition of potent opioids tends to prolong the recovery, but fentanyl up to 1.5 µgm/kg does not delay emergence when given immediately before induction$^{12}$.

In all the poor countries like ours, cost-effectiveness is an influential consideration related to the health-care consumers along with other aspects. In this study, it is found that the expense for propofol is Tk-142.00±6.00/= per patient. One ampoule costing Tk-260/= contains 200 mg of propofol while the average requirement is 140±12 mg for induction; rest of the drug has to discard for its higher risk of contamination$^{13}$. So, actual expenditure per case goes high due to system loss. On the other hand, in group-B, the average cost of induction agents is Tk-37.88±1.37/= per case, i.e. 26.66% of that of group-A (Table-V). Moreover, thiopentone remains stable for 24-36 hours after mixing and is permitted to use in several patients from multi-dose vials$^{14}$ and thereby seems more economic. Tab midazolam (7.5 mg) charges simply Tk-10/= and most of the patients require 15 mg
which costs Tk-20/= only. So, the cost of these co-
induction agents is significantly less than that of
injection propofol.

Under the condition of present study, we could
conclude that oral midazolam and intravenous
thiopental sodium induction in day care surgery is
highly cost effective than propofol alone induction
agent without any significant changes in
hemodynamics, recovery scores as well as time to
ready to go home.
