Serum Copper and Plasma Protein Status in Normal Pregnancy

Nushrat Noor¹, Nasim Jahan², Nayma Sultana³

Abstract

Background: Gradual alteration of serum copper and some plasma protein levels may occur with advancement of pregnancy, which is associated with increased maternal and infant morbidity and mortality. Objective: To observe serum copper and plasma protein levels in normal pregnant women of different trimesters in order to find out their nutritional status. Methods: This cross sectional study was carried out in the Department of Physiology, Sir Salimullah Medical College (SSMC), Dhaka, between 1st January 2010 and December 2010. Ninety normal pregnant women of different trimesters with age 20-30 years were included in the study group. They were selected from Out Patient Department of Obstetrics and Gynaecology, SSMC. Age matched 30 non-pregnant women were taken as control. Serum copper level was measured by Spectrophotometric method, serum total protein and albumin levels were estimated by standard method. Statistical analysis was done by one way ANOVA, Bonferroni and Pearson’s correlation coefficient test as applicable. Results: Serum Cu levels were significantly higher in all trimesters of pregnant women compared to control. Again, this value was significantly higher in 3rd trimester than that of in 1st and 2nd trimester and also in 2nd trimester than that of in 1st trimester. In addition, mean serum total protein level was significantly lower in 3rd trimester than control but no statistically significant difference was observed among different trimesters. Again, mean serum albumin level was significantly lower in 2nd and 3rd trimester than 1st trimester and control. In addition, serum Cu concentration showed significant positive correlation with different trimesters of gestation. Conclusion: This study reveals that hypercupremia along with hypoproteinemia occur in pregnant women from 1st to 3rd trimester of gestation. This gradual alteration of micro and macronutrients become more profound with advancement of pregnancy.

Key words: Serum copper, Plasma protein, Trimester, Pregnancy.

Introduction

Pregnancy is a period of increased metabolic demands, with changes in the woman’s physiology and the requirements of a growing fetus. During this time, improper stores or intake of micronutrients can have adverse effects on the mother such as anemia, hypertension, complication of labor and even death. Furthermore the fetus can be affected resulting in stillbirth, pre-term delivery, IUGR.

Received: August 2012; Accepted: November 2012
Different researchers demonstrated that micro and macro nutrients are essential for the development of fetus. In pregnancy many minerals like zinc, copper, calcium and magnesium are transferred from mother to the fetus. Copper is essential for neural function. It forms an integral component of many metalloenzymes including amine oxidase, cytochrome oxidase, super-oxide dismutase and tyrosinase. In addition, copper is also involved in the synthesis of hemoglobin, formation of collagen, skeletal development, maintenance of the myelin sheath and in immune function. Maternal copper deficiency can cause infertility, abortion and still birth. Copper deficiency during pregnancy can result in delivery of offspring with congenital abnormalities of the nervous system. It has been reported that more than 50% of human conception fail to implant and of those implanted, approximately 30% fail to reach term due to copper deficiency. However, during pregnancy serum copper level increases from about 80 to 155 µg/dl to about 118 to 302 µg/dl by the end of the 3rd trimester. This increase of copper may be due to an increase of ceruloplasmin as a result of elevated level of estrogen during pregnancy. Again, less diffusion of maternal serum Cu through the placenta may also cause hypercupremia in pregnant women. However, excess copper level in pregnancy can be associated with intrauterine growth retardation in fetus and preeclampsia along with some neurological diseases in mother. Moreover, persistently high copper levels may contribute to postpartum depression due to the effects of metals on nervous tissue. Excess copper in the brain, can alter the balance of dopamine and norepinephrine, two mood-regulating neurotransmitters.

It has been observed that copper level was significantly higher in pregnant women than that of non pregnant women. They also found that copper level increased gradually and significantly from the 1st trimester to the 3rd trimester. The maximum increased level of copper was observed during 3rd trimester of pregnancy. Some other group of investigators also reported that pregnant women of 28 to 32 weeks of gestation had lower serum copper levels in comparison to the pregnant women of gestational age 32 to 36 weeks. A significant positive correlation was found between gestational age and serum copper level. On the contrary, a decreased serum Cu level was also found in 3rd trimester when compared to that of in 1st and 2nd trimester of normal pregnant women.

Furthermore, some nutritional deficiencies such as deficiency of protein, vitamins etc. may also be responsible for preterm delivery especially in developing countries. In addition to this, protein deficiency especially deficiency of albumin and globulin may also be responsible for alteration of maternal plasma Cu concentration, as they act as Cu-binding vehicle. Some researchers found significantly lower levels of serum total protein and albumin in some pre-term mother in comparison to those of non- pregnant women and also of full-term mother. So, pregnancy is often associated with adequate level of all the nutrients like iron, copper, zinc, proteins etc. and inappropriate supply of one of these may affect pregnancy, delivery and outcome of pregnancy.

A change of micro and macronutrient status in women of reproductive age is recognized as a major public health problem in our country. Pregnant women are vulnerable to nutritional deficiencies because of the increased demand during pregnancy. Although some work on role of copper and plasma proteins on preterm delivery was done in our country, but little is known about serum copper and protein levels in different trimesters of normal pregnancy.
Therefore, the present study has been undertaken to estimate serum copper and protein concentrations in different trimesters of gestation. It is expected that findings of this study would give a guideline to the obstetrician for better management of the pregnant women which may prevent maternal and fetal morbidity and mortality and also may reduce the risk of complication during and after delivery.

Methods
This cross sectional study was carried out in the Department of Physiology, Sir Salimullah Medical College (SSMC), Dhaka between 1st January 2010 and 31st December 2010. Study subjects were selected by following simple random sampling procedure and the protocol of this study was approved by Institutional Ethics Committee (IEC) of SSMC. Total number of 90 normal pregnant women of different trimesters age 20-30 years was enrolled in the study group (Group B). They were subdivided into group B₁ (n=30) 1st trimester, group B₂ (n=30) 2nd trimester and group B₃ (n=30) 3rd trimester. Age matched 30 apparently healthy non-pregnant women (group A) was served as control group. The pregnant women were collected from Out Patient Department of and Obstetrics and Gynaecology, SSMC and non-pregnant women by personal contact. Serum copper level was measured by Spectrophotometric method, serum total protein and albumin levels were estimated by standard laboratory method. The statistical analysis was done by One-way ANOVA (Post Hoc), Bonferroni and Pearson’s correlation coefficient test by using SPSS, version-16.

Results
All the groups were matched for age. Mean (+SD) of Age and BMI of different groups are shown in (Table I).

The mean (+SD) serum Cu level was significantly higher in all groups of pregnant women than that of non-pregnant women. Again, this value was significantly (p<0.001) higher in 3rd trimester than that of 1st and 2nd trimester and also in 2nd trimester than that of 1st trimester (Table II).

Again, mean serum total protein level was significantly (p<0.01) lower in 3rd trimester than that of non-pregnant women. Whereas, this level was almost similar and no statistically significant difference was observed among the other groups. Again, mean serum albumin level was significantly lower in 2nd and 3rd trimester than that of non-pregnant women (p<0.001) and also of 1st trimester (p<0.05). Whereas mean serum globulin level was almost similar and showed no statistically significant difference of this value among the groups (Table II).

Moreover, serum Cu concentration was positively correlated (r=0.784) with different trimesters of gestation and this relationship was statistically significant (p<0.001) (Figure 1).
In the present study, increased serum Cu level has been found during different trimesters of pregnant women and maximum increased value was observed in the 3rd trimester. This finding is consistent with that of some other researchers. On the contrary, serum Cu level was found lower in the 3rd trimester of gestation when compared to that of in 1st and 2nd trimester of pregnant women. The researchers suggested that this might be due to hemodilution. Again, serum Cu concentration has shown significant positive correlation with different trimesters of gestation in present study. Similar observation is also made by other investigators.

### Discussion

In the present study, increased serum Cu level has been found during different trimesters of pregnant women and maximum increased value was observed in the 3rd trimester. This finding is in consistent with that of some other researchers. On the contrary, serum Cu level was found lower in the 3rd trimester of gestation when compared to that of in 1st and 2nd trimester of pregnant women. The researchers suggested that this might be due to hemodilution. Again, serum Cu concentration has shown significant positive correlation with different trimesters of gestation in present study. Similar observation is also made by other investigators.
However, hypercupremia during 3\textsuperscript{rd} trimester of pregnancy may be due to mobilization of copper from maternal tissues, especially from the liver for its utilization during fetal development\textsuperscript{21}. Again, it has been suggested that increased serum Cu during 3\textsuperscript{rd} trimester of pregnancy may be due to increase in carrier protein, ceruloplasmin in response to elevated level of estrogen\textsuperscript{13}. In addition to this decreased biliary copper excretion induced by hormonal changes, may lead to an increase in serum Cu level during pregnancy\textsuperscript{10}. Moreover, an inverse metabolic relationship exists between zinc and copper which may also be responsible for elevated plasma copper levels in the presence of lower plasma zinc during pregnancy\textsuperscript{22}. During last months of pregnancy the plasma progesterone exceeds the normal limit. This hormone increases plasma copper, necessary for placental maturation\textsuperscript{4}.

In addition, in the present study a gradual decrease in total protein and albumin levels were also observed in different trimesters of pregnancy. It has been suggested that, pregnant women in developing countries consume diets with a lower quantity of protein, minerals and vitamins\textsuperscript{23}. This inadequate dietary intake may be responsible for hypoproteinemia and hypoalbuminemia during pregnancy\textsuperscript{2}.

In the present study, a gradual increase in serum copper level was observed in pregnant women of different trimesters, which was more pronounced in 3\textsuperscript{rd} trimester. This high serum Cu level in pregnant women of the present series are may be due to increased concentration of ceruloplasmin in response to stimulation by elevated level of estrogen during pregnancy. But this cannot be elucidated from the present study as serum concentration of ceruloplasmin was not measured. Furthermore, significant positive correlation of serum Cu level with different trimesters of gestation indicating the changes of this micronutrient on each trimester of gestation which is more marked in 3\textsuperscript{rd} trimester. Again, hypoproteinemia and hypoalbuminemia of the study subjects indicating their poor nutritional status. However, the exact mechanism involved for this gradual alteration of serum copper and plasma protein level in different trimesters of pregnancy cannot be find out from this type of study due to time and financial constrains. So, a further study on this field is required for clarification.

**Conclusion**
From this study, it can be concluded that gradual hypercupremia and hypoproteinemia occur in pregnant women from 1\textsuperscript{st} to 3\textsuperscript{rd} trimester of gestation. This gradual alteration of micro and macronutrients become more profound with advancement of pregnancy may be due to their nutritional deficiency and high demand during pregnancy.

**Acknowledgement**
Authors of this study are thankful to the authority of Department of Biochemistry, BSMMU for the cooperation regarding laboratory facility they provided. The authors acknowledge the partial financial support from the research grant of DGHS of Bangladesh. The authors are also thankful to all of study subjects for their active and cordial cooperation to carry out the study.
