Preterm Delivery: Role of Zinc

Abstract

Background: Preterm delivery is a very challenging obstetric complication in Bangladesh. Reduced serum zinc (Zn) concentration of the pregnant mother may have some role in causing preterm delivery.

Objectives: To measure serum zinc level in preterm delivery mother and their respective neonates to observe their status.

Methods: This cross sectional study was carried out in the Department of Physiology, Sir Salimullah Medical College, Mitford Hospital, Dhaka, during the period of 1st January to 31st December 2009. A total 136 subjects were included in this study, of whom 27 were full term delivery mother with their respective neonates (group B), treated as control group and another 27 were preterm delivery mothers with their respective neonates (group C), treated as study group. Age ranged of preterm and full term mother were from 20-40 years. Again, 28 non pregnant women with age range from 20-30 years were taken as reference value (groupa A). Statistical analysis was done by using appropriate method as applicable.

Results: Mean serum zinc level was significantly (p<0.001) lower in preterm mother in comparison to that of full term mother and also in preterm neonates than that of full term neonates. Serum total protein and albumin were significantly (p<0.001) lower in preterm mother than those of full term mother and also in preterm neonates than those of their respective mothers and full term neonates. Again, maternal serum zinc level showed positive correlation with birth weight of neonates and also with zinc concentration of neonatal blood. Conclusions: The present study revealed a lower level of serum zinc in pre-term delivery mother and their neonates. These hypozincemia may be responsible for low birth weight of the fetus.

Key Words: Zinc, preterm

Introduction

Preterm delivery can be defined as the onset of labor prior to 37 weeks of gestation¹. Incidence of preterm labor is 23.3% in India² and in Bangladesh 16.7%³. Nutritional deficiencies such as deficiency of proteins, vitamins and some minerals especially zinc (Zn) may be responsible for preterm delivery particularly in the developing countries². Trace elements needed in minute quantities are essential for development and normal function of the body as well as for healthy fetal outcome. Zinc plays a definitive role in this regard⁴. Deficiency of this micronutrient causes a number of maternal and fetal complications during pregnancy and delivery⁵,⁶.

The serum Zn concentration may decrease during pregnancy mainly due to hemodilution, decreased availability of Zn binding protein, hormonal changes during pregnancy and decreased binding affinity to albumin⁷,⁸. Serum Zn concentration begins to decline in early
pregnancy and continues till term where it is about 35% lower than that in the non pregnant female.

Low maternal zinc status during pregnancy causes 3.5 to 7 fold increased risk for premature rupture of amniotic membrane and induce preterm labor. Again, a low intake of Zn during pregnancy may cause increased risk of low birth weight as well as preterm delivery.

Low maternal serum Zn concentration during pregnancy may be associated with pregnancy induced hypertension, abruptio placentae, inefficient uterine contraction, prolonged or non-progressive labor and maternal haemorrhage and infections. Again, severe maternal Zn deficiency may cause spontaneous abortion, congenital abnormalities such as anencephaly, hydrocephaly and stressful parturition.

Preterm delivery is a challenging obstetric problem in our country. Deficiency of Zn may have some role on this regard. Some study has been done regarding this matter in abroad. But no published data is available in our country on this aspect. Therefore the present study has been undertaken to measure serum zinc level in preterm delivery mother and their respective neonates to observe their status.

Methods
The present cross sectional study was carried out in the Department of Physiology, Sir Salimullah Medical College, Mitford Hospital, Dhaka, during the period of 1st January 2009 to 31st December 2009. A total number of 136 subjects were included in this study, and all of them belonged to lower socioeconomic status. Among them 54 were full term delivery mother with their respective neonates (group B), treated as control group. Of them 27 were full term mother (B₁) and 27 were neonates of the respective mother (B₂). Again, another 54 were preterm delivery mothers with their respective neonates (group C), and treated as study group. Of them 27 were preterm mother (C₁) and 27 were neonates of the respective mother (C₂). Age ranged of preterm and full term mother were from 20-40 years. Again, 28 non pregnant women with age range from 20-30 years were taken as reference value (group A). Protocol of this study was approved by the ethical committee of SSMC. Subjects having history of any microbial and metabolic diseases were excluded from the study. All the pregnant mothers were collected from emergency labor ward in Sir Salimullah Medical College, Mitford Hospital and non-pregnant women were selected from personal contact. After selection of the subjects, the objectives and benefits of the study were explained and written informed consent was taken from the subjects. All ethical norms were maintained. Institutional permission was taken from the Director of the Hospital. Detail personal, dietetic, medical, family, socio economic, occupational histories were taken and a thorough clinical examination were done and all information was recorded in a standard prefixed questionnaire. With all aseptic precautions 5ml of maternal blood were drawn from medial cubital vein by disposable syringe and 5 ml of neonatal blood were collected from placental end of cord immediately after delivery. Blood was centrifuged at 3000 rpm for 20 minutes. After that supernatant serum was collected in labeled eppendorf tube and from it 1 ml of serum was transferred in a plain glass test tube for estimation of serum total protein and albumin by standard laboratory technique in the laboratory of Physiology Department, SSMC, Dhaka. Another 1 ml was taken in deionized tube for estimation of serum zinc level by spectrophotometric method in the laboratory of Atomic Energy Commission. The statistical analysis was done by Independent-samples t test and Pearson’s correlation by using SPSS, Version-15.

Results
Antropometric data of the subjects are presented in Table I. This table shows that mean height (p<0.01), weight (p<0.001) and BMI (p<0.001) were significantly lower in group C₁ in comparison to that group B₁. In the present study...
birth weight of group C2 was significantly (p<0.001) lower than that of group B2. Whereas, the weights of full term neonates were within normal reference value.

Mean serum zinc level was significantly (p<0.001) lower in group C1 in comparison to that of group B1 and also in group C2 than that of group B2. Again, serum Zn level was significantly (p<0.001) higher in B2 in comparison to that of B1. No statistically significant difference of this level was observed between C1 vs C2 (Table II).

Mean serum total protein and albumin were significantly (p<0.001) lower in group C1 than those of group B1. Again, these values were significantly (p<0.001) lower in group C2 in comparison to those of group B2. On the other hand, mean serum globulin levels were almost similar and no statistically significant difference were observed between group B1 vs C1, B1 vs B2 and B2 vs C2.

Again, correlations of maternal serum zinc concentration with birth weight of their neonates and with Zn concentration of neonatal blood are presented in figure 1 and 2. Maternal serum zinc level showed positive correlation with birth weight in group B \( (r=0.025, p>0.05) \) and group C \( (r=0.514, p<0.05) \) which was statistically significant only in group C. On the other hand, maternal serum zinc level showed positive correlation with neonatal blood in group B \( (r=0.108 p>0.05) \) and group C \( (r=0.257, p>0.05) \).
In this study, serum zinc deficiencies have been found both in preterm delivery mother and their neonates. Again, low birth weights have been found in this group of neonates. These findings are in agreement with those of some other researchers. Pregnant women in developing countries consume diets with a lower quantity of protein, minerals, and vitamins. An inadequate dietary intake before and during pregnancy is high risk factor both for mother and fetus, which may be responsible for preterm delivery as well as for low birth weight of the neonates.

However, lower level of serum Zn in preterm mother might be due to its low dietary intake, increased body demand, malabsorption, increased urinary excretion and impaired utilization. Grain products containing dietary fiber and phytate decrease its absorption. Again, increased urinary excretion due to decreased availability of binding protein causes lower serum Zn level. It has also been suggested that low serum Zn concentration during pregnancy might be due to physiological hemodilution, decreased in Zn binding capacity, increase transfer of Zn from the mother to the fetus. In addition to fetal accumulation, Zn is also deposited in placenta and amniotic fluid, leading to the lowering of maternal serum Zn. Hypozincemia in preterm neonates might be due to increased demand of this micronutrient for fetal growth, erythropoiesis and immaturity of the liver to synthesize Zn binding protein.

Group B: (Control)
- Group B1 = Healthy full term delivery mother
- Group B2 = Full term neonates of the respective mother

Group C: (Study)
- Group C1 = Preterm delivery mother
- Group C2 = Preterm neonates of the respective mother

ns= not significant
**=significant at p<0.01

Figure 1: Correlation of maternal serum zinc (Zn) concentration with the birth weight of their neonates in group B (n=54) and group C (n=54)

Figure 2: Correlation of maternal serum zinc (Zn) concentration with zinc concentration of neonatal blood in group B (n=54) and group C (n=54)
It has been suggested that Zn deficiency may lead to defective function of estrogen which may impair uterine contractions, cervical dilation and amniotic fluid integrity. Furthermore, low maternal Zn status during pregnancy may cause premature rupture of amniotic membrane which in turn induces preterm labor\textsuperscript{10,11}. Again, several investigators demonstrated the relationship between low serum Zn concentration during pregnancy and small for gestational age\textsuperscript{11,12}. In the present study, hypozincemia was observed in preterm delivery mother is most likely due to decreased levels of binding protein as the observed levels of them were lower. In addition, poor socio-economic status of the study subjects also indicates inadequate food intake especially low dietary protein. Again, low birth weight of preterm neonates in this study may be due to their hypozincemia, as evidenced by their measured values in cord blood. This hypozincemia of preterm neonates of present study may be due to low maternal serum Zn concentration, as evidenced by the positive correlation of maternal serum Zn concentration with birth weight of neonates are also suggestive of necessity of this micronutrient for healthy outcome.

**Conclusion**

This study concludes that, hypozincemia may be present in preterm mother and their neonates. This study also tried to prove the effects of low serum Zn levels on fetal outcome, as supported by their low birth weight. So, along with zinc supplementation, protein enrich diet is also necessary for some zinc deficient pregnant women to prevent preterm delivery and for healthy fetal outcome.

**Acknowledgement**

Authors of this study are thankful to the authority of Atomic Energy Commission for the cooperation regarding laboratory facility they provided. I would also express my sincere thanks to the Director of Medical Education for the valuable fund which was enormously supported for completing the research work.
