Abstract:
The paper investigates the role of complete velocity slip on the axisymmetric peristaltic transport of Ellis fluid through a uniform flexible tube considering the long wavelength and tiny Reynolds number assumptions. The equations governing the axisymmetric flow are solved and provided the analytical expressions for axial velocity, stream function, pressure difference for shear thickening and shear thinning fluids and the effect of emerging parameters on the pressure rise with time averaged flux and stream line patterns have been discussed graphically. The trapping phenomenon results showed that the size of trapping bolus enhances with increasing values of first and second slip parameters.

Keywords: Ellis fluid, complete slip, shear thickening behavior, shear thinning behavior.

1. Introduction

Peristalsis is an important transport phenomenon characterized by the contraction and relaxation of flexible tube and naturally observed in tubular organs of human body to transport the fluids. Peristaltic flow is an essential mechanism for fluid transport in tubular organs for example, the oesophagus, the gastrointestinal tract, the ureter and the urethra. Recent detailed exposition on the peristalsis can be found in research of (Saravana et al., 2018, Hayat et al., 2019, Manjunatha et al., 2019, Noreen and Kousar, 2019, Akram et al., 2019).
The peristaltic propulsion is also a novel and mechanical displacement method to transfer the liquid within a flexible tube. In rotor peristaltic mechanism, when the rotor turns, the tube under compression closes forcing the fluid being pumped to move through the tube. As the tube opens and returns to its starting state after passing the fluid and further the fluid is induced to pump. The action also helps to propel the fluid without the contamination of outside environment. It is built to pump various fluid types in different marine structures or vessels, industrial and in medical environments. The mechanism is found in marine uses connected to pumping of slurry and in emptying of bilges and tanks of the boats and other vessels.

The transporting liquid includes water, abrasive or corrosive, shear thickening agents such as gels and oxidizers. Shear thinning agents such as paints and polymer solutions. The behavior of flow which mimics the shear-thinning fluid and/or shear thickening fluid is Power-law model. When the deviations from the model are significantly demonstrated at low shear rates, it is appropriate to use Ellis model. The limiting value behavior of power-law fluid model under consideration, Ellis proposed the three parameter fluid model to exhibit the flow characteristics over a small shear rate ranges by swapping the roles of shear stress and strain rates.

The flow of an Ellis fluid through a circular tube with an impermeable wall have been explored by Longwell (1966). Ali et al. (2015) reported the peristaltic transport of non-Newtonian Ellis fluid through a channel. Abbas et al. (2017) demonstrated the peristaltic blood of Ellis fluid through a non-uniform channel with compliant walls. Recently, Kumar et al. (2018) addressed the peristaltic pumping of an Ellis fluid model in an inclined tube with wall properties. Ali et al. (2019) studied the electro-osmotic peristaltic flow of an Ellis fluid in contact with a Newtonian fluid through an axisymmetric tube.

Motivated by the influence of above works, we investigated the peristaltic transport of an Ellis fluid in a circular tube with the modelling of complete wall slip under small values of Reynolds number. The velocity field, stream function, volume flow rate and pressure rise over one wavelength are determined. The effects of Ellis parameter $\eta_1$ and the two slip parameters on the pumping characteristics and stream line patterns are depicted graphically.

2. Mathematical Formulation

The Ellis equation model is explored under the consideration of work (Ali et al., 2019) and Rathy (1976) as

$$\eta_0 \tau_{\eta} + \eta_1 \left| \tau_{\eta} \right|^{n-1} \tau_{\eta} = \frac{dw}{dr}$$

(1)

The model has three adjustable set of positive parameters namely the zero shear viscosity $\eta_0$, and $\eta_1$ and $n$. When suitably chosen $n$ greater than unity, the model approaches Newtonian fluid for small values of extra stress tensor component $\tau_{\eta}$. On the other hand, when $n$ is subjected to less than unity, Newtonian model approaches for large values of $\tau_{\eta}$. The model is highly flexible and recovers the Newtonian fluid model as $\eta_1 \rightarrow 0$ and the power-law model as $\eta_0 \rightarrow 0$.

We consider the peristaltic flow associated with an incompressible Ellis fluid through a circular tube of radius $a$ (see Fig. 1) in presence of complete wall slip. The axisymmetric inertia free flow is generated by the sinusoidal wave train propagation with wave speed ‘$c$’ along the tube in the cylindrical geometry.

The geometry of the wall surface is defined as

$$R = H(Z,t) = a + b \sin \frac{2\pi}{\lambda} (Z - ct)$$

(2)

where $b$ refers the amplitude, $\lambda$ refers wave length.
Peristaltic pumping of Ellis fluid through a flexible tube with complete slip effects

Such a flow rises unsteady in the laboratory frame \((r, \theta, z)\) and attain steady in the wave frame \((r, \theta, z)\). The transformation between the lab frame and wave frame of reference leads to the following

\[
r = R, \theta = \theta, z = Z - ct, \Psi = \frac{R^2}{2} \text{ and } p(Z, t) = p(z)
\]

where \(\psi\) and \(\Psi\) denotes the wave and the laboratory frame stream functions respectively.

Further, we define the following dimensionless quantities.

\[
\eta = H \frac{b}{a}; \phi = \frac{b}{a} \frac{w}{r} = \frac{c}{\lambda}; \bar{c} = \frac{c}{\lambda}; \bar{w} = \frac{w}{\lambda} \frac{\psi}{\pi \alpha \lambda}; \bar{w} = \frac{w}{\lambda} \frac{1}{\lambda} \frac{\psi}{\pi \alpha \lambda}; \bar{u} = -\frac{1}{\lambda} \frac{\psi}{\pi \alpha \lambda}; \bar{\tau} = \frac{\eta \alpha \tau_{rc}}{c}.
\]

where \(\bar{w}\) is the axial velocity component in the wave frame, \(\beta_1\) is the first slip parameter and \(\beta_2\) is the second slip parameter.

Under the lubrication approach and using the above non-dimensional quantities, we arrive the equation of motion as (omitting the bars):

\[
\frac{1}{r} \frac{\partial}{\partial r} (r \tau_{rc}) = \frac{\partial \bar{p}}{\partial \tau_{rc}} = \frac{\partial \bar{p}}{\partial \tau_{rc}},
\]

The appropriate boundary conditions for the concern problem of study are

\[
\tau_{rc} \text{ is finite at } r = 0
\]

\[
w = -1 - \beta_1 \frac{\partial w}{\partial r} - \beta_2 \frac{\partial^2 w}{\partial r^2} \quad \text{at } r = h
\]

\[
\psi = 0 \quad \text{at } r = 0
\]

When the flow takes place past a rough surface, it is well known that the usual no slip condition is not valid at the surface \(r = h(z)\). The slip at such rough surfaces has been remarked through several slip conditions such as Navier (1827), Beavers and Joseph (1967), Saffman (1971), Vajravelu et al. (2013), Saravana et al. (2017) and Prasad and Yasa (2020). In view of the flow on such surfaces, the improved boundary condition Eq. (8) proposed by Ebaid et al. (2017) is introduced at the bounding wall incorporating the complete slip.

3. Solution Procedure

Simplifying the Eq. (5) and Eq. (6) by imposing the boundary conditions Eq. (7) and Eq. (8) leads to the existence of velocity field as

\[
w = -1 - P \left( \frac{h^2}{4} + \frac{\beta_2}{2} + \frac{\beta_2 h}{2} - \frac{r^2}{4} \right) - P \left( \frac{\eta h^{n+1}}{2^n (n+1)} + \frac{\eta nh^{n+1}}{2^n} + \frac{\eta h^{n+1}}{2^n} - \frac{\eta h^{n+1}}{2^n (n+1)} \right)
\]

in which \(P = \frac{\partial \bar{p}}{\partial \tau_{rc}}\).
Integrating the Eq. (10) by applying the condition (9) leads to the stream function as

$$\psi = -P^n\left(\frac{\eta_1 h^{n+1}r^2}{2^n(n+1)} + \frac{\beta_2 \eta_1 n h^{n-1}r^2}{2^{n+1}} + \frac{\beta_1 \eta_1 h^n r^2}{2^n - \frac{\eta_1 r^{n+3}}{2^n(n+1)(n+3)}} - \frac{P^n h^2 r^2}{8} - \frac{\beta_2 hr^2}{4} - \frac{\beta_1 hr^2}{4} - \frac{r^4}{16} - \frac{r^2}{2}\right)$$

(11)

The rate of volume flow $q$ through each cross section in the wave frame is presented by

$$q = 2 \int_0^h w(r) dr$$

$$= -h^2 - P\left(\frac{h^4}{8} + \frac{\beta_2 h^2}{2} + \frac{\beta_1 h^3}{2}\right) - \frac{P^n}{2^n}\left(\frac{\eta_1 h^{n+3}}{n+3} + \beta_2 \eta_1 nh^{n-1} + \beta_1 \eta_1 h^{n+2}\right)$$

(12)

The instantaneous volume flow rate $Q(z,t)$ in the laboratory frame is given by

$$Q(z,t) = 2\int_0^h (w+1) r dr$$

$$= q + h^2$$

$$= P\left(\frac{h^4}{8} + \frac{\beta_2 h^2}{2} + \frac{\beta_1 h^3}{2}\right) - \frac{P^n}{2^n}\left(\frac{\eta_1 h^{n+3}}{n+3} + \beta_2 \eta_1 nh^{n+1} + \beta_1 \eta_1 h^{n+2}\right)$$

(13)

Averaging Eq. (13) over one period gives the time-averaged volume flow rate $\overline{Q}$ is followed by

$$\overline{Q} = \frac{2}{T} \int_0^T \int_0^h (w+1) r dr dt$$

$$= q + 1 + \frac{1}{T} \int_0^T h^2 dt$$

$$= q + 1 + \frac{\phi^2}{2}$$

(14)

Choosing Ellis parameter $\eta_1 = 0$ in Eq. (13), the corresponding results are identical to the peristaltic motion of an incompressible Newtonian fluid in a flexible tube with complete slip mentioned below as

$$\frac{dp}{dz} = -\frac{q + h^2}{h^4 + \frac{\beta_2 h^2}{2} + \frac{\beta_1 h^3}{2}}$$

(15)

Further, by considering $\beta_2 = 0$ in the Eq. (15), we have the pressure gradient for the peristaltic pumping of Newtonian fluid in a circular tube with complete slip as

$$\frac{dp}{dz} = -\frac{q + h^2}{h^4 + \frac{\beta_1 h^3}{2}}$$

(16)

Employing $\beta_1 = \beta_2 = 0$ in the Eq. (15), we find that

$$\frac{dp}{dz} = -8(q + h^2)$$

(17)

The result deducted agree with the corresponding result of Jaffrin and Shapiro (1971) for the peristaltic transport of an incompressible Newtonian fluid in a tube

Eq. (13) permits a nonlinear relationship in pressure gradient, thus the expression examined independently for $n < 1$ and $n > 1$ which corresponds to shear thickening and shear thinning fluids respectively.
We now turn to the pumping characteristics for particular set of non-negative values of $n$, say, $n = \frac{1}{2}$ and 2 are respectively to shear thickening and shear thinning fluids.

In particular, if one considers shear thickening value $n = \frac{1}{2}$, then pumping characteristics is explored as

$$\frac{dP_1}{dz} = \pm \left[ \frac{784}{h^2} (q + h^2) \left( 1 + \frac{4\beta_1}{h^2} + \frac{4\beta_1}{h} \right) - \frac{128}{h} \eta_1 \left( 1 + \frac{7\beta_1}{4h^2} + \frac{7\beta_1}{2h} \right)^2 \right] \left( 98 \left( 1 + \frac{4\beta_1}{h^2} + \frac{4\beta_1}{h} \right) \right)^{-1}$$

$$= \pm \left[ \sqrt{\frac{784}{h^2} (q + h^2) \left( 1 + \frac{4\beta_1}{h^2} + \frac{4\beta_1}{h} \right) - \frac{128}{h} \eta_1 \left( 1 + \frac{7\beta_1}{4h^2} + \frac{7\beta_1}{2h} \right)^2 \right]} \left( \frac{56}{h^2} (q + h^2) \right)^{-1}$$

If the respective shear thinning value is $n = 2$, then the pumping characteristics is given by

$$\frac{dP_2}{dz} = -\frac{5h^4}{\frac{1}{2} \left( 1 + \frac{4\beta_2}{h^2} + \frac{4\beta_2}{h} \right) \pm \left( 5h^4 \left( 1 + \frac{4\beta_2}{h^2} + \frac{4\beta_2}{h} \right) \right) - 320\eta_1 h^5 \left( 1 + \frac{2\beta_2}{h^2} + \frac{\beta_2}{h} \right) (q + h^2) \right]}$$

$$= \frac{4\eta_1 h^5 \left( 1 + \frac{2\beta_2}{h^2} + \frac{\beta_2}{h} \right)}$$

Eq. (18) is integrated with respect to $z$ per wavelength for obtaining Pressure rise $\Delta P$ across one wavelength for shear thickening fluid as

$$\Delta P_1 = \int_0^1 \frac{dP_1}{dz} dz$$

Eq. (19) is integrated with respect to $z$ per wavelength for obtaining Pressure rise $\Delta P$ across one wavelength for shear thinning fluid as

$$\Delta P_2 = \int_0^1 \frac{dP_2}{dz} dz$$

4. Results and Discussion

The effect of Ellis parameter $\eta_1$, first slip parameter $\beta_1$ and second slip parameter $\beta_2$ on the pressure rise with time-averaged flux $\bar{Q}$ for shear thickening and shear thinning fluids are analyzed and depicted graphically. From Eq. (20), we have explored the pressure rise $\Delta P_1$ for a shear thickening fluid as a function of time-averaged flux $\bar{Q}$. Fig. 2 depicts the pressure rise $\Delta P_1$ variation of Ellis parameter $\eta_1$ on shear thickening fluid with time-averaged flux. We notice that $\Delta P_1$ has been enhanced with the growth of Ellis parameter. The curve $\eta_1 = 0$ corresponds to Newtonian fluid with complete slip. Figs. 3 and 4 illustrate the impact of the two slip parameters on the variation of $\Delta P_1$ with time-averaged flux. We see that the pressure rise gradually increases with increasing first slip parameter $\beta_1$ and second slip parameter $\beta_2$. The curve $\beta_2 = 0$ in Fig. 4 represents the peristaltic flow of Ellis fluid (shear thickening) with partial slip. The greater the second slip parameter the more the pressure rise against which the pump works for a shear thickening fluid.

From Eq. (21), we have explored the pressure difference $\Delta P_2$ for a shear thinning fluid as a function of time-averaged flux $\bar{Q}$. Figs. 5-7 are plotted to observe the distribution of pressure rise across the tube with $\bar{Q}$ for
different values of $\eta_1$, $\beta_1$ and $\beta_2$. Fig. 5 indicates $\Delta P_2$ with $\bar{Q}$ for small values of Ellis parameter. We found that increasing $\eta_1$ decreases the pumping performance in pumping region ($\Delta P > 0$) and the pumping curves coincides in free pumping ($\Delta P = 0$) and co-pumping region ($\Delta P < 0$). Figs. 6 and 7 illustrate the effect of the slip parameters on the variation of $\Delta P_2$ with time-averaged flux. It is found that increasing first slip parameter $\beta_1$ and second slip parameter $\beta_2$ decreases the pumping and free pumping. The curve $\beta_2 = 0$ in Fig. 7 represents the peristaltic flow of Ellis fluid (shear thinning) with partial slip.

The streamline patterns are illustrated from Eq. (11). The effects of Ellis fluid parameter $\eta_1$ corresponding to shear thinning fluid are depicted in Fig. 8(a-c). We found that the trapping bolus size decreases with the enhancement of $\eta_1$. The effects of power-law index parameter $n$ on trapping phenomenon are demonstrated in Fig. 9(a-c). From these figures, we found that the volume of the trapped bolus decreases when the fluid changes from shear thickening to shear thinning. There is also a greater number of trapped boluses occur for the Newtonian fluid ($n = 1$). The influence of slip parameters on streamline patterns are visualized in Figs. 10 and 11. It is evident that the size of trapping bolus strengthens with increasing first and second slip parameters.

5. Conclusions

In this paper, we demonstrated the task of incorporating the complete velocity slip conditions at the uniform tube walls of the peristaltic flow of an Ellis fluid under the constraint of long wavelength and small Reynolds number. The interesting findings are as follows

- Pressure rise for shear thickening fluid increases with large values of Ellis parameter.
- Pressure rise for shear thickening fluid increases with the growth of first slip parameter and second slip parameter.
- Increasing Ellis parameter decreases the pumping performance in pumping region and the pumping curves coincides in free pumping and co-pumping region.
- The size of trapping bolus enhances with growth of first and second slip parameters.
- The trapping bolus size declines with large Ellis fluid parameter variation.
