Abstract
Background: Proof of rape depends not only on the physical findings of the victims but also to the subjective intentions of the assailants. Objective: The purpose of the present study was to find out the medicolegal findings of rape victims in order to point out the visible loopholes of the procedure. Methodology: This was a cross sectional descriptive type of study which was done in the Dept. of Forensic Medicine, Dhaka Medical College, Dhaka, Bangladesh from January to December 2016 with maintaining ethical issues. Rape cases from 23 police stations of Dhaka Metropolitan area were sent for medicolegal examination and victims who ultimately agreed to do medicolegal examinations were examined and opinions were given regarding the issues. Results: A total number of 69 cases from 23 police stations of Dhaka Metropolitan area were studied. In this study, majority (70.0%) of the victims was within 11 to 20 years of age and 65.0% of the victims were unmarried. Almost 68.0% of the victims were examined within 7 days followed by 32.0% of the victims after 7 days to beyond one month after rape; however, 48.0% of the victims showed sign of recent hymen tear with bruise and abrasion followed by 52.0% showed sign of old hymen tear. Spermatozoa were not found in any of the specimen of high vaginal swab. Conclusion: In conclusion, teenage unmarried girl are the most common victim of rape cases. Keywords: Rape; medicolegal; victim.

Introduction
The word ‘rape’ is derived from latin term ‘rapio’ which means to seize. Thus rape literally implies forcible seizure¹. Rape is defined as physically forced or otherwise coerced penetration - even if slight - of the vulva or anus, using a penis, other body parts or an object. The attempt to do so is known as attempted rape². No age is immune of rape. But children are more frequently raped due to their less resistance along with the belief that venereal diseases are cured by sexual intercourse with a virgin³. In many cases, positive physical findings may not be found in alleged rape. Rape can occur without causing any injury and as such negative evidence does not exclude rape⁴. The doctor should mention only the negative facts; but should not give his opinion that rape has not been committed. Corroboration by eye witness or circumstantial evidence is necessary in such cases⁴. Rape is a heinous crime that destroys the hope and aspiration of a victim. It is such a complex issue that
cannot be demonstrated easily. Proof of rape depends not only in the physical findings of the victims but also to the subjective intentions of the assailants. Moreover, in many times, negative physical findings along with lack of witness of the incidence, create problems in courts of law to bring out justice for the victims as everybody is innocent until incidence is proved beyond reasonable doubt in the court.

Methodology
This was a descriptive type of cross-sectional study conducted in the Department of Forensic Medicine at Dhaka Medical College, Dhaka, Bangladesh from January to December 2016 with maintaining ethical issues. Rape victims who agreed to do medicolegal examinations were recorded as victims of alleged sexual assaults. Victims of alleged rape cases from 23 Metropolitan police stations of Dhaka, Bangladesh were sent for medicolegal examinations within the above mentioned period. After physical examination, radiological report and microbiological report opinion was given whether the signs of forceful sexual intercourse were present or not.

Results
A total number of 69 cases from 23 police stations of Dhaka Metropolitan area were studied. Table 1 showed that 70% of the victims was belonged to 11 to 20 years of age group followed by 21 to 30 years of age 14.0%.

Table 5 showed that no spermatozoa were found in any specimen of high vaginal swab.

Discussion
The magnitude of rape or sexual harassment is high all over the world. However, it comes a little in front of us most of the times. In the majority of countries with available data; less than 40% of the women who experience sexual assault seek help of any sort. Among who do, most work to family and friends and very few look to formal institutions and mechanisms, such as police and health services. Less than 10% of those women seeking no help for experience of volume sought help by appealing to the police. The under reporting of cases of sexual assaults are mainly due to social stigma; prejudice with regard to the chances of marriage, publicity in press, embarrassment in court, doubt in local law enforcement, risk of losing the love
and respect of society. In this study, it has been found that majority (70.0%) of the victims was 11 to 20 years of age and 65.0% of the victims were unmarried. It reflects that young, unmarried girls are usually targeted for rape; 45.0% of the victims was examined within 3 days after rape. According to table 3, majority, almost 48.0% of the victims were examined after 3 days to within one month after rape followed by 7.0% beyond one month. That is why, signs of forceful sexual intercourse were supposed to be absent in majority cases; 52% of the victims presented with old hymeneal tear with no signs of abrasion and bruise and 48% of the victims showed recent hymen tear with abrasion and bruise. Spermatozoa were not found in our study in any of the specimen of high vaginal swab.

Saha et al reported that 53.94% of the victims’ age was within 16 to 20 years followed by 26.32% belonged to 11-15 years. So, majority, 80.26% of the victims were 11 to 20 years of age and 71.05% victims were unmarried. Majority of the victims (65.79%) had the signs of recent hymen tear. Ali et al in their study showed that majority (60.0%) of the victims was within 11 to 20 years of age and 64.8% of the victims were unmarried. Significant percentage (59.0%) of the victims was sent within 3 days of rape for medicolegal examination. But positive physical findings were found only in 27.5% cases. Majority (72.4%) had no signs of forceful sexual intercourse. Another study by Al Azad et al reported that majority (69.57%) of the victims were within 11 to 20 years of age and 78.69% victims were unmarried. 38.69% of the victims were sent for medicolegal examination within same day of rape. However, as a whole half (50.0%) of the victims were sent within 3 days for medicolegal examination. The rest half were sent beyond 3days to 4 weeks.

In a study conducted by Arif et al that 60.8% of the victims were within 11 to 20 years of age and 70.9% of the victims were unmarried. 24.3% of the victims were presented for medicolegal examination within 24 to 48 hours of incidents but as a whole, only 45.1% of the victims were sent within 3 days of the incident and the majority, 55% were sent after 3 days to more than 1 month. Majority of the victims (77.6%) showed old hymen tears. Spermatozoa were found in 18.2% of the cases.

Vadysigie et al showed that 43% of the victims were 12 to 16 years of age followed by 16 to 20 years 21%. So, majority (64.0%) of the victims were within 12 to 20 years of age. Only 29.0% of the victims were sent within 3 days of incident for medicolegal examination. Significant percentage (71.0%) of the victims were sent after 3 days to beyond 1 month of incident for medicolegal opinion. Akinlusi et al showed that 83.6% were below 19 years and over 60.0% of victims presented after 24 hours of assault. Spermatozoa were not found in this present study in any cases among the high vaginal swab which is similar to Al-Azad et al. Absence of spermatozoa in the high vaginal swab does not mean that sexual intercourse has not taken place. These may be due to non-emission, aspermia, previous vasectomy, very old age or poor technique by the examining doctor. Moreover, ejaculation outside vagina, using barrier method can be the factor of failure of detection of spermatozoa in high vaginal swab. Spermatozoa were found in 17.6% and 30.3% cases reported by Islam et al and Grossin et al respectively.

**Conclusion**

Finally, it can be said that this study reflects that teenage unmarried girls are usually targeted for rape. But, majority of the victims were examined after 3 days to within one month after rape. That is why, signs of forceful sexual intercourse were supposed to be absent in majority cases. Spermatozoa were not found in our study in any of the specimen of high vaginal swab.

**References**

Rape is defined as physically forced or means to seize. Thus rape literally implies forcible
physical seizure of a victim. It is such a complex issue that physical findings may not be found in alleged rape. Rape victims who agreed to do medicolegal examinations were recorded as victims of alleged sexual assaults. Victims of alleged rape cases from 23 police stations of Dhaka Metropolitan area were studied. Table 1 showed that recent forceful sexual intercourse was found in 48% cases.

Results

Spermatozoa were not found in our study in any of the specimen of high vaginal swab. But, majority of the victims were examined after 3 days of the incident and the rest half were sent beyond 3 days to more than 1 month.

Discussion

Saha et al7 reported that 53.94% of the victims’ age was below 11 years. Majority of the victims (77.6%) showed old hymen tears. Spermatozoa were found in 18.2% of the victims.

Conclusion

Finally, it can be said that this study reflects that majority (60.0%) of the victims was within 11 to 20 years of age and 70.9% of victims were sent within 3 days of rape for medicolegal examination. But 55% were sent after 3 days to more than 1 month.
