Introduction

Stroke is the leading cause of mortality and morbidity worldwide. Globally, stroke is the second leading cause of death above the age of 60 years and the fifth leading cause in people aged 15 to 59 years of age. In many developed countries, the incidence of stroke declining but the actual number is increasing because of ageing populations. Bangladesh is a developing country with 150 million population of which one third is in older age group. In a survey conducted in Dhaka city and some parts of Bangladesh revealed crude prevalence of stroke is 3 per 1000 population.

Abstract

**Background:** Plasma D-Dimer is a biomarker of thrombo-embolism. **Objective:** The purpose of the present study was to see the plasma D-dimer level in different types of acute ischaemic stroke patients.

**Methodology:** This cross-sectional study was conducted in the Department of Neurology & Department of Internal Medicine at the Department of Neurology at the Dhaka Medical College Hospital, Dhaka, Bangladesh from July 2010 to June 2012 for a period of two (02) years. Patients with ischemic stroke with history within 7 days attending in the stroke clinic of Department of Neurology or admitted in the Department of Neurology and Internal Medicine through the outpatient and emergency Department of Dhaka Medical College Hospital (DMCH) were selected as study population for this study. Analysis of plasma D-Dimer was done in the Department of Hematology of DMCH.

**Result:** A total of 50 cases were recruited for this study. There were 24.0% lacunar infarcts, 40.0% atherothrombotic and 36.0% embolic infarcts in the study group. Highest level of plasma D-Dimer was observed in embolic (1700±964 ηg/ml) followed by atherothrombotic group (536±234 ηg/ml). The plasma D-Dimer was lowest (100±0 ηg/ml) in lacunar group. Concentration of Plasma D-Dimer showed significant correlation with clinical diagnosis in different subtypes of ischemic stroke (r=0.902; p=0.001) and also with risk factors, example, diabetes (r=0.319; p=0.012) and valvular heart disease (r=0.281; p=0.024), but no significant correlation with clinical diagnosis alone or with clinical diagnosis plus risk factors. Clinical judgment alone or with clinical judgment plus risk factors.

**Conclusion:** In conclusion plasma D-Dimer is an important biomarker in the clinical diagnosis and subtypes of ischemic stroke patients. [Journal of National Institute of Neurosciences Bangladesh, 2019; 5(1):13-17]

Keywords: Plasma D-dimer level; types; acute ischaemic stroke
Plasma level of D-Dimer is an index of fibrin generation, which is a cross linked fibrin degraded products. Moreover, tissue plasminogen activator is needed for formation of plasmin from plasminogen. Several studies show that substantial alternations in hemostatic function in there cohort of patients with cerebral ischemia. These consist of sustained increase in platelet activation, increased thrombin activity acutely, and decrease in fibrinolytic activity. D-Dimer levels were significantly elevated in patients with acute ischemic stroke, indicating increased fibrin formation and it is consistent with the concept that an occlusive fibrin thrombus, either embolic or form in situ, is involved in the pathogenesis of ischemic stroke. D-Dimer levels is highest in the subjects with cardioembolic stroke, less high in patients with large vessel disease and not elevated in lacunar stroke or TIA. These findings suggest that plasma D-Dimer levels correlate with the size of the fibrin thrombus, and thus patients with lacunar disease and TIA either have thrombi too small to produce detectable elevations of plasma D-Dimer, or that fibrin formation does not occur to significant extent. In this context, this present study was undertaken to see the plasma D-dimer level in different types of acute ischaemic stroke patients.

**Methodology**

This study was designed as analytical cross-sectional study. This study was conducted in the Department of Neurology & Department of Internal Medicine at Dhaka Medical College Hospital, Dhaka, Bangladesh from July 2010 to June 2012 for a period of two (02) years. Patients with ischemic stroke with history within 7 days attending in the stroke clinic of Department of Neurology or admitted in the Department of Neurology and Internal Medicine through the outpatient and emergency Department of Dhaka Medical College Hospital (DMCH) were selected as study population for this study. The selection of the study was performed by purposive sampling technique. Patients admitted with signs and symptoms of acute ischemic stroke, patients diagnosed as a case of acute ischemic stroke by CT scan of brain were included for this study. Patients below 18 years of age, concomitant use of anticoagulant in stroke patient and patients with co-morbidity that affects D-Dimer level were excluded from this study. Ischemic stroke patients fulfilling the inclusion and exclusion criteria were enrolled for the study, examined by the investigator. Clinical diagnosis of stroke was done according to National Institute of Neurological Disorders and Stroke (NINDS) criteria. Then CT scan was done to confirm the diagnosis. Analysis of plasma D-Dimer was done in the Department of Hematology of DMCH. Commercially prepared reagent ‘CTM D-Dimer Latex Kit’ was used for analysis. CTM D-Dimer latex test is intended for the rapid qualitative or semi quantitative evaluation of circulating derivatives of cross linked fibrin degradation products (XL-FDP) in human plasma. CTM D-Dimer latex is a rapid agglutination assay utilizing latex beads coupled with a highly specific D-Dimer monoclonal antibody. Undiluted plasma D-Dimer concentration was regarded as Positive or Negative depending on plasma value, either greater or less 200 ng/ml respectively. Quantitative measurement was done by serial dilution method. All collected data were related with clinical history, physical examination, biochemical and radiological findings with Serum D-Dimer was analyzed. Statistical analysis was performed with the help of computer by using statistical package for social science (SPSS). All qualitative data were expressed in frequency and percentage. ANOVA test was performed among the mean with SD among the subtypes of ischaemic stroke. The levels of significance accepted at P value ≤ 0.05. Permission from the Ethical Committee was taken before conducting the study.

**Results**

A total of 50 cases were recruited for this study of which 16% patients were from 18 to 40 years age group. The maximum number of patients was found in more than 60 years of age group which is 32%. The mean (±SD) of ages were 58.36±14.80 in the ischemic stroke (Table 1).

Discussion

Diagnosis of stroke is still challenging and is mostly based on clinical findings\(^2\). Patients developed a sudden onset of focal neurological deficit may have a stroke or may have one of several possible ’stroke mimic’ conditions including the aura of migraine, postictal deficits following a focal seizures, metabolic derangements (hypoglycaemia), an anamnestic spell (recrudescence of prior deficit in the setting of an infection or metabolic derangement), mass lesion or a conversion reaction\(^7\).

The most of the biomarkers of stroke are panel biomarker and studies correlating there plasma concentration to stroke phenotypes has not been established. Some of these are found to be increased in the cerebrospinal fluid of stroke patients but serum concentrations do not differ from those control patients\(^5\). The ideal biomarker would clearly distinguish stroke from stroke mimics and have consistent results within and between laboratories. It would be a blood or serum or plasma test and would be diagnostic within the first few hour of the onset of stroke with a quick automated assay\(^8\).

Stroke biomarkers most useful when combined with clinical judgment alone or with clinical judgment plus brain imaging\(^9\). Fibrin D-Dimer could be an ideal hemostatic marker for early diagnosis of stroke in this ground. Raised plasma D-Dimer is a constant finding in thrombogenic disorder, especially when they affect the venous system. Several authors reported that the increased level of D-Dimer always related to the acute phase of ischemic stroke and related this to worse vital and functional prognosis and to a higher risk of recurrence during follow up\(^10\). Study conducted by Barber et al\(^11\) have concluded that plasma D-Dimer is an independent marker of acute progressing stroke. It is may be positive as early as 30 minutes of stroke and remains positive up to one month. D-Dimer level could be estimated from the blood samples which were collected within 7 days of stroke for assessing stroke progression. Estimation of D-Dimer may also play role in differentiating stroke subtypes\(^12\). There are other several conditions associated with increased D-Dimer,
such as pregnancy, after surgery, trauma, pre-eclampsia, malignancy, infection, disseminated intravascular coagulation (DIC), sickle cell disease, pulmonary thromboembolism, deep vein thrombosis (DVT) and acute coronary syndrome. Plasma D-Dimer level was measured in 50 acute ischemic stroke patients and was compared with the age and sex matched healthy control groups. The results of the present study demonstrate that D-Dimer level significantly differ among the stroke subtypes after an acute ischemic event and the measurement of D-Dimer levels can be reliable in the early diagnosis of the mechanism of underlying cause. In a series of 291 consecutive stroke patients in Bangladesh revealed mean age was 57.9 years and incidence of stroke was 80.0% in male patients. This study reveals mean age of stroke as 58.36±14.80 years.

Ischemic stroke has been classified according to the Oxfordshire community stroke project criteria based on clinical symptoms, location, and extent of cerebral infarction and sub divided into 4 clinical categories, total anterior circulation infarcts (TACI), partial anterior circulation infarcts (PACI), lacunar infarcts (LACI), and posterior circulation infarcts (POCI). Several studies have found that an increased concentration of plasma D-Dimer level in acute ischemic stroke patients. This D-Dimer value showed weak to moderate correlation, supports a link between inflammation, hypercoagubility and fibrin turnover in ischemic stroke patients. This present study reveals that mean concentration of plasma D-Dimer is 804±120 ng/ml in all ischemic stroke patients irrespective of subtypes and a value 126±16 ng/ml in control group. Furthermore, the plasma D-Dimer (ng/ml) concentration was 1700±964, 536±234 and 100±0 in embolic, atherothrombotic and lacunar group respectively. Values of plasma D-Dimer varied significantly in different subtypes of stroke in this study although lowest concentration in lacunar group is contrary to the one study.

Plasma D-Dimer value is identified in patients at high risk for stroke progression and remain as an independent predictor. Raised D-Dimer is a constant finding in thrombogenic disorders. In a study by Barber and his colleagues in 2004 reported increased levels of D-Dimer during the acute phase of ischemic stroke and related to this worse vital function and functional prognosis and to a higher risk of recurrence during follow-up. In addition, plasma D-Dimer value is highest in association with cardioembolic mechanism. A controlled study reported that patients with cardioembolic stroke had raised mean levels of D-Dimer, and has higher risk of new embolisms. Alvarez-Perez et al concluded in a study that there was a continuous activation of coagulation and fibrinolysis characterized by raised D-Dimer in ischemic stroke. This study is taken for early identification of acute ischemic stroke patients in Bangladeshi population, thus stroke patients may be benefited with thrombolytic therapy with reduction of substantial morbidity and mortality. This study suggests that plasma D-Dimer level is a potential biomarker in acute ischemic stroke and also helpful in categorizing the subtypes. Estimation of plasma D-Dimer level and adjunct to CT scan will strengthen the diagnosis of acute ischemic stroke which will help in therapeutic management.

Present study has some limitations. A small number of cases were included in this study. Follow up was not done. Stroke progression was not evaluated with further measurement of plasma D-Dimer level. A prospective randomized study with greater number of patients will help to ascertain further role of plasma D-Dimer in acute ischemic stroke.

**Conclusion**

This study indicates that raised plasma D-Dimer is a constant finding in acute phase of ischemic stroke. Measurement of plasma D-Dimer is simple and can be an adjunct to diagnosis of acute ischemic stroke. Thus measuring plasma D-Dimer level will further strengthen the clinical diagnosis of ischemic stroke particularly where CT scan could not be done. Plasma D-Dimer estimation should be done in acute ischemic stroke patients, especially in embolic and atherothrombotic subgroups for thrombolysis and interventions.
