Prevention of Hypertension in Bangladesh: A Review
TUHIN BISWAS,1 SHEIKH MOHAMMED SHARIFUL ISLAM,1,2 ANWAR ISLAM3

Abstract
Hypertension is a major public health problem globally in both the developed and developing countries. Hypertension leads to cardiovascular diseases, stroke, kidney failure and is the leading cause of mortality and morbidity globally. The risk factors for hypertension, which can mostly be prevented through simple health promotion and preventive measures are mostly known. However, papers documenting the strategies for prevention of hypertension in Bangladesh is not available. The aim of this review study was to identify and discuss different approaches to prevent hypertension in Bangladesh. We performed a systematic search using electronic as well as manual method for published and unpublished reports of prevention of hypertension. We then identified and discussed prevention strategies for hypertension suitable for Bangladesh context. Although several methods have shown to prevent hypertension, the challenge remains in implementing these methods in resource poor settings. Integrated action based on comprehensive policy and stepwise implementation should be adopted taking into consideration of local needs. Hypertension prevention should focus on awareness generation, health promotion and reduction of common risk factors using a combination of population based approach and targeted individual interventions. Consorted actions should be taken as a priority to prevent hypertension through intersectoral, multidisciplinary and multilevel approach by the Government, Non-Government Organizations (NGOs), civil societies and create greater awareness among the population for a healthy life-style.

Key words: Prevention; Hypertension; Blood Pressure; Cardiovascular Diseases; Bangladesh

Introduction
Hypertension or high blood pressure (BP) is a silent killer and the most common risk factor for cardiovascular diseases (CVD), chronic kidney diseases and stroke.1 More than a quarter of the world adult population is currently hypertensive and this figure is projected to rise to 30%, by 2025.2 CVDs are the leading cause of death and disability worldwide with about 80% of the deaths occurring in developing countries.3 Furthermore, the onset of hypertension and CVD occurs at a relatively younger age in Asians and consequently the age at which people die of CVD is considerably younger than in developed countries, leading to widespread social and economic hardship.4

The prevalence of hypertension varies considerably by country: 20% in the USA, and 25–50% in different regions in Europe.5 Reliable data related to the prevalence, incidence and mortality of hypertension are not available from Bangladesh. A meta-analysis, a population based study and a recently published survey found the prevalence of hypertension in Bangladesh 11.3%, 18.6%, and 20.1%, respectively.6 The Bangladesh non-communicable diseases (NCD) risk factor survey in 2010 reported the prevalence of hypertension 17.9% (18.5% in men and 17.3% in women). Hypertension is probably more common in elderly population. A Bangladeshi study reported the prevalence of hypertension 65% in general, 75% in urban and 53% in rural areas.7 A recent study among senior citizens showed that 44.8% were hypertensive.8 Another study reported that hypertension is equally prevalent in rural population among the diabetics, the prevalence of systolic hypertension was 23.2% and diastolic hypertension 13.6%. A recent study by Shariful Islam and colleagues showed that systolic hypertension was significantly associated with diabetes complications [OR 0.809, 95% CI 0.666–0.981 (p-value 0.031) after controlling for all other effect.10

Overweight, sedentary lifestyle, unhealthy diet, salt intake, diabetes and smoking are among the common risk factors

for hypertension in Bangladesh. Hypertension and its complications, which are mostly preventable though simple health promotion and preventive measures, pose a serious threat to the health systems and socio-economic condition of a country. Hypertension prevention therefore is of great public health importance in Bangladesh and other developing countries. Several papers have described different methods of prevention of hypertension. However, papers summarizing the different approaches and effectiveness of these methods are scarce in Bangladesh. In this paper, we review and discuss the different prevention approaches for hypertension from Bangladesh prospective.

**Methods**

The paper is based on review of published and unpublished data on prevention of hypertension in Bangladesh and other countries. A systematic search was performed using electronic as well as manual method. The electronic search was done with Pub Med, GoggleScholar, Medline and Bangla Jol. Search strategies used subject headings and key words (Hypertension, prevention, Bangladesh). We also reviewed reports from different government sources, non-government organizations (NGOs) and different hospital reports in Bangladesh. References list of relevant reviews were used to identify studies and the cited literature was reviewed. Among published articles, we excluded papers that did not describe the prevention strategies of hypertension.

**Results**

**Diagnosis and screening:** Proper diagnosis with accurate measuring devices is an important first step in the management of hypertension. Screening not only detects hypertension but also provides an opportunity for patient education and therapy. In light of the growing epidemic of CVD in the developing world, the World Health Organization (WHO) recommends that opportunistic screening of BP is done at every visit to the physician’s office. The diagnosis of hypertension should not be made on one single measurement in a physician’s office. If BP is elevated, it must be reconfirmed at subsequent visits within one month unless there is a hypertensive emergency. According to the 7th report of the joint national committee on prevention, detection, evaluation and treatment of high blood pressure (JNC 7) hypertension can be classified as follows:

<table>
<thead>
<tr>
<th>Category</th>
<th>Systolic BP (mmHg)</th>
<th>Diastolic BP (mmHg)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Normal</td>
<td>&lt;120</td>
<td>&lt;80</td>
</tr>
<tr>
<td>Pre hypertension</td>
<td>120-139</td>
<td>80-89</td>
</tr>
<tr>
<td>Stage 1 hypertension</td>
<td>140-159</td>
<td>90-99</td>
</tr>
<tr>
<td>Stage 2 hypertension</td>
<td>≥160</td>
<td>≥100</td>
</tr>
</tbody>
</table>

**Population-based strategy:** A population-based approach aimed at achieving a downward shift in the distribution of BP in the general population is an important component for any comprehensive plan to prevent hypertension. A small decrement in the distribution of systolic BP is likely to result in a substantial reduction in the burden of hypertension-related illness. In an analysis based on Framingham heart study experience, Cook and colleagues concluded that a 2 mmHg reduction in the population average of diastolic BP for white USA residents 35 to 64 years of age would result in a 17 percent decrease in the prevalence of hypertension, a 14 percent reduction in the risk of stroke and transient ischemic attacks, and a 6 percent reduction in the risk of coronary heart diseases (CHD). Public health approaches, such as lowering sodium content or caloric density in the food supply, and providing attractive, safe, and convenient opportunities for exercise are ideal population-based approaches for reduction of average BP in the community. Enhancing access to appropriate facilities (parks, walking trails, bike paths) and to effective behavior change models is a useful strategy for increasing physical activity in the general population.

**Intensive targeted strategy:** More intensive targeted approaches, aimed at achieving a greater reduction in BP in those who are most likely to develop hypertension, complement the previously mentioned population based strategies for prevention of hypertension. Groups at high risk for hypertension include those with a high-normal BP, a family history of hypertension, overweight or obesity, a sedentary lifestyle, excess intake of dietary sodium and/or insufficient intake of potassium, and/or excess consumption of alcohol.

**Weight loss:** A comprehensive review of the evidence supporting the value of modest reductions in body weight is provided in the clinical guidelines for the identification, evaluation, and treatment of overweight and obesity in adults. He j et al. reported on the experience of 181 normotensive persons who had participated in phase I trials of hypertension prevention. During the initial 18 months of active intervention those assigned to the weight loss group reduced their body weight by 7.7 lb (3.5 kg) and their systolic and diastolic BPs by 5.8 and 3.2 mmHg, respectively. After 7 years of follow-up, the incidence of hypertension was 18.9 percent in the weight loss group and 40.5 percent in the control group. These findings suggest that weight loss interventions produce benefits that persist long after the cessation of the active intervention. In phase II trials of hypertension prevention, the 595 participants assigned to a weight loss counseling intervention experienced a 21 percent...
Dietary sodium reduction: At least three meta-analysis of the efficacy of reduced sodium intake in lowering BP have been published since 1993. In all three reports, sodium reduction was associated with a small but significant reduction in systolic BP in normotensive persons. In a meta-analysis of 12 randomized controlled trials conducted in 1,689 normotensive participants, Cutler and colleagues estimated that an average reduction of 77 mmol/d in dietary intake of sodium resulted in a 1.9 mmHg (95% CI, 1.2–2.6 mmHg) decrement in systolic BP and a 1.1 mmHg (95% CI, 0.6–1.6 mmHg) decline in diastolic BP.

In a randomized controlled trial (dietary approaches to stop hypertension [DASH]-sodium trial) conducted in 412 persons with an average systolic BP of 120 to 159 mmHg and an average diastolic BP of 80 to 95 mmHg, a reduction in sodium intake from a high level (mean urinary sodium excretion, 142 mmol/d) to an intermediate level (mean urinary sodium excretion, 107 mmol/d) reduced systolic BP by 4.6 mmHg during consumption of the control diet (p<.001) and 1.7 mmHg reduction during consumption of the dash diet (p<.01). The effects of sodium reduction were greater for those who ate the typical American diet, compared with those on the dash diet. These findings are consistent with current national recommendations for a moderately low intake of dietary sodium (no more than 100 mmol/d: approximately <6 g of sodium chloride or <2.4 g of sodium per day) by all americans and suggest that an even lower level of dietary sodium intake may result in a greater reduction in BP. In a large, long-term community-based randomized controlled trial, Whelton et al. reported that a moderate reduction of dietary sodium intake resulted in an additional 4.3 mmHg reduction in systolic BP among older.

Increased physical activity: A meta-analysis by Whelton et al. showed a 4.04 mmHg (95% CI, 2.75–5.32) reduction in systolic BP in those assigned to aerobic exercise compared with the control group. The magnitude of the intervention effect appears to be independent of the intensity of the exercise program. In the physical activity and health: a report of the surgeon general it is recommended that persons exercise for at least 30 minutes on most, if not all, days of the week.

Dietary sodium reduction: A meta-analysis of the efficacy of reduced sodium intake in lowering BP have been published since 1993. In all three reports, sodium reduction was associated with a small but significant reduction in systolic BP in normotensive persons. In a meta-analysis of 12 randomized controlled trials conducted in 1,689 normotensive participants, Cutler and colleagues estimated that an average reduction of 77 mmol/d in dietary intake of sodium resulted in a 1.9 mmHg (95% CI, 1.2–2.6 mmHg) decrement in systolic BP and a 1.1 mmHg (95% CI, 0.6–1.6 mmHg) decline in diastolic BP.

In a randomized controlled trial (dietary approaches to stop hypertension [DASH]-sodium trial) conducted in 412 persons with an average systolic BP of 120 to 159 mmHg and an average diastolic BP of 80 to 95 mmHg, a reduction in sodium intake from a high level (mean urinary sodium excretion, 142 mmol/d) to an intermediate level (mean urinary sodium excretion, 107 mmol/d) reduced systolic BP by 4.6 mmHg during consumption of the control diet (p<.001) and 1.7 mmHg reduction during consumption of the dash diet (p<.01). The effects of sodium reduction were greater for those who ate the typical American diet, compared with those on the dash diet. These findings are consistent with current national recommendations for a moderately low intake of dietary sodium (no more than 100 mmol/d: approximately <6 g of sodium chloride or <2.4 g of sodium per day) by all americans and suggest that an even lower level of dietary sodium intake may result in a greater reduction in BP. In a large, long-term community-based randomized controlled trial, Whelton et al. reported that a moderate reduction of dietary sodium intake resulted in an additional 4.3 mmHg reduction in systolic BP among older.

Persons with hypertension whose BPs were well controlled by a single antihypertensive medication for those assigned to a combined sodium reduction and weight loss intervention, the corresponding additional reduction in systolic BP was 5.5 mmHg. The need for antihypertensive medication during a subsequent 18 month period of followup was reduced by 31% and 53% in those assigned to sodium reduction and combined sodium reduction and weight loss, respectively. In the NHANES epidemiologic follow-up study, he et al. reported that a 100 mmol higher level of sodium intake in overweight persons was associated with a 32% increase in stroke incidence, 89% increase in stroke mortality, 44% increase in CHD mortality, 61% increase in CVD mortality, and 39% increase in mortality from all causes. In Finland a prospective population-based cohort study showed that the hazard ratios for CHD, CVD, and all-cause mortality, associated with a 100 mmol higher level of 24 h urinary sodium excretion, were 1.51 (95% CI, 1.14–2.00), 1.45 (95% CI, 1.14–1.84), and 1.26 (95% CI, 1.06–1.50), respectively. There was a significant interaction between sodium excretion and body mass index for cardiovascular and total mortality, with sodium being a stronger predictor of mortality in men who were overweight. These data support the premise that a lower intake of dietary sodium reduces the risk of subsequent CVD, especially in those who are also overweight.

Potassium supplementation: Clinical trials and meta-analysis indicate that potassium supplementation lowers BP in both hypertensive and normotensive persons. In a meta-analysis of the results from 12 trials with 1,049 normotensive participants, Whelton et al. reported that potassium supplementation (median, 75 mmol/d) lowered systolic BP by 1.8 mmHg (95% CI, 0.6–2.9) and Diastolic BP by 1.0 mmHg (95% CI, 0.0–2.1). The effects of potassium supplementation appeared greater in those with higher levels of sodium intake.

Dietary measures: The DASH and DASH-sodium trials used dietary interventions that incorporated several nutritional recommendations for lowering BP. In the 8 week DASH trial, study participants with a systolic BP less than 160 mmHg and a diastolic BP between 80 and 95 mmHg level of urinary sodium excretion (141 mmol/d). A significant reduction in diastolic BP was also observed. Furthermore, the beneficial effects of the DASH diet and the DASH diet
with reduced sodium occurred broadly in all major subgroups of the population.\textsuperscript{30}

**Calcium supplementation:** Consistent with previous observations, a recent metaanalysis of randomized controlled clinical trials suggests that calcium supplementation results in only a small reduction in BP and this effect has only been observed in those with hypertension.\textsuperscript{30} However, for general health, adequate calcium intake (1,000–1,200 mg/d for adults) as a dietary component is recommended.\textsuperscript{31}

**Fish oil supplementation:** Two meta-analysis of clinical trials indicate that supplementation with relatively high doses of omega-3 polyunsaturated fatty acids (omega-3 pufa) lowers BP in hypertensive patients, especially in those with untreated hypertension.\textsuperscript{32,33} In normotensive persons, however, the effect seems to be small. In a pooled analysis of 11 trials with 728 normotensive participants, Appel et al. reported that fish oil supplementation (3.4 g/d) lowered systolic BP by only 1.0 mmHg (95 percent ci, 0.0–2.0) and diastolic BP by 0.5 mmHg (95\% CI, –0.2–1.2).\textsuperscript{32} Adverse effects, including eructation and a fishy taste, were more common in those assigned to fish oil capsules. Although evidence for a BP-lowering effect of fish oil is modest, observational epidemiological studies and clinical trials have suggested that an increased intake of fish oil may reduce the risk of CHD and stroke.\textsuperscript{32,33,34}

**Herbal supplements:** There has been considerable increase in the use of herbal products in the United States. Results from the 1998–1999 Slone survey indicated that about 14% of the US adults were taking herbal products.\textsuperscript{35} The 10 most commonly used herbal products are ginseng, ginkobiloba extract, allium sativum, glucosamine, St. John’s wort, echinacea augustifolia, lecithin, chondroitin, creatine, and serenoa repens.\textsuperscript{33} Dietary supplements including herbs do not undergo the same stringent regulatory approval process as drugs. Food and drug laws do not require demonstration of safety and efficacy to support legal marketing of dietary supplements. There is a lack of standardization among brands of supplements, and the bioactive ingredient of products can vary widely. Few clinical trial reports are available to support the use of herbal supplements in the prevention or treatment of high BP or heart disease. Health care professionals should ask their patients about the use of herbal products and consider the possibility of herb-drug interactions.

**Primary prevention in children:** There is ample evidence that hypertension begins in childhood. Children with higher than average BP levels early in life are more likely to develop hypertension later in life. Efforts to prevent BP from increasing in childhood are prudent and best accomplished by application of the same lifestyle approaches used to prevent and treat hypertension in adults.\textsuperscript{36} Accordingly, school administrators are encouraged to examine their lunch menus and promote the use of heart healthy foods. Parents are encouraged to read food labels and make wise choices for lunches prepared at home. In addition, school curricula should include health education programs that promote healthy life style.

**Barriers and challenges in Bangladesh**
Less than a third of hypertensive patients receive recommended levels of treatment even in rich and developed nations.\textsuperscript{37} Low levels of awareness and inadequacy of treatment are of an even greater magnitude in the developing world particularly in Bangladesh. This underscores the large gap between available evidence and clinical practice that could be improved to reduce the widespread health consequences of uncontrolled hypertension particularly in the Bangladesh. Hypertensive patients in Bangladesh have a close association with dyslipidemia and need measurement of blood pressure and lipid profile at regular intervals to prevent car-diovascular disease, stroke, and other comorbidities.\textsuperscript{38}

**Economic burden**
Multiplicity of health care providers including alternative caregivers, lack of capacity and affordability of physician services in our country adversely impacts hypertension care. Patients often pay out-of-pocket for their health care.\textsuperscript{39} Besides imposing considerable economic burden, this often drives many families into poverty particularly those with chronic conditions such as hypertension requiring lifelong care. Consequently, many stop treatment altogether or become non-adherent.

**Prevention of hypertension in the community**
The major thrust of management of hypertension in a developing country settings such as Bangladesh should be on primary prevention efforts through a comprehensive population based approach directed at lifestyle changes (a healthy appropriate calorie diet which is low in saturated fat and salt additives and rich in fruits and vegetables, increased physical activity, and a smoking free society), properly balanced with a high risk approach of cost effective clinical care. The health care delivery system needs to emphasize early detection and treatment of individual patients at high risk with the most cost effective drugs. Existing networks of primary health care centers should be optimally utilized and categories of healthcare providers, who can detect, educate and monitor hypertensive patients can be expanded to include nurses and multipurpose health workers. Though the current
networks focus primarily on communicable diseases and reproductive health, networks could be used for opportunistic screening for hypertension and CVD risk assessment. A good model in optimal use of existing services for hypertension management was reported from South Africa, where a nurse led clinical protocol based in primary care clinics succeeded in achieving hypertension control in 68% of patients.22

Limitation
Data related to hypertension in Bangladesh are often insufficient, suffer from statistical flaws, and are not readily available. Many articles were published in local, non-indexed journals, not available online, and difficult to gather. In literature review we included only papers in English. Further studies analyzing the cost-effectiveness of interventions to prevent hypertension in Bangladesh and other countries would provide better evidence.

Conclusion
Hypertension is one of the leading cause of morbidity and mortality in Bangladesh. Although several methods have shown to prevent hypertension, the challenge remains in implementing these methods in resource poor settings. Integrated action based on comprehensive policy and stepwise implementation should be adopted taking into consideration of local needs. Hypertension prevention should focus on awareness generation, health promotion and reduction of common risk factors using a combination of population based approach and targeted individual interventions. Consortred actions should be taken as a priority to prevent hypertension through intersectoral, multidisciplinary and multilevel approach by the Government, Non-Government Organizations (NGOs), civil societies and create greater awareness among the population for a healthy life-style.
