Risk Factors and Outcome of Obstructed Labour at a tertiary care Hospital

Islam JA, Ara G, Choudhury FR

Abstract

Background: Obstructed labour is one of the most common preventable cause of maternal and prenatal morbidity and mortality in developing countries. Objective: The purpose of the present study was to determine the risk factors as well as to assess the outcome of obstructed labour. Method: This cross sectional study was conducted in the Department of Gynecology & Obstetrics at Shaheed Ziaur Rahman Medical College Hospital, Bogra during the period from January 2007 to December 2007. One hundred and five cases with features of obstructed labour were selected as per inclusion and exclusion criteria in a consecutive method. A detailed history included socio-demographic feature, obstetric history, features of obstruction, intrapartum events were recorded to detect risk factors. Condition of patients, mode of delivery, preoperative and post operative complications, maternal and fetal outcomes were recorded. Results: A total number of 3171 deliveries were conducted during this period and 132 cases of obstructed labour were found constituting an incidence of 4.2%. The highest frequency was found among the unbooked, primigravid patients that were illiterate or only having primary education level. The commonest cause was cephalo-pelvic disproportion (47.5%) followed by fetal malposition (25.7%) and malpresentation (24.8%). The majority of the patients were between 25-29 years, caesarean section was the most common mode of delivery (78.09%). Maternal morbidity due to different complication accounted for 76.19% of the case while the fetal morbidity was 51.31% of the cases. The maternal mortality was 1% and prenatal mortality was 24.76%. Conclusion: In this study the incidence of obstructed labour was very high. The commonest cause was cephalo-pelvic disproportion followed by fetal malposition and malpresentation.

Key words: Obstructed labour, cephalopelvic disproportion, prenatal morbidity

Introduction

Obstructed labour results from failure of descent of fetal presenting part in the birth canal for mechanical region, in spite of good uterine contraction and it leads to various maternal and fetal complications. It is one of the most common preventable cause of maternal and prenatal morbidity and mortality in developing countries. It accounts for about 8% of total maternal death in Bangladesh. Several studies from other developing countries found an incidence ranging from 2-8% of all hospital deliveries. Its occurrence is regarded as a sign of poor level of obstetric practice in any environment because obstructed labour is due to mechanical difficulties which takes place where access to proper obstetric care might not be available or utilized.

In booked patients obstructed labour is prevented by elective caesarean section where dystocia is anticipated, and the use of partogram in labour management is early recourse to emergency caesarean section. At present, most of the women in this country don't have timely access to EOC and only 5% of expected complications reach the medical facilities. This is because of three delay model that is delay in decision to take care, delay to reach the health care centre, and delay to receive adequate treatment. In Bangladesh 80% people live in rural areas, where most of the deliveries (90%) are conducted at home. Traditional birth attendants (TBA) conduct 63% of deliveries of which 38% are conducted by trained TBA and 25% are conducted by untrained ones. In Bangladesh there is a high prevalence of teenage pregnancies and grand-multiparity due to early marriage. Repeated pregnancies out side the hospital by untrained midwives leads to obstructed labour which is a common cause of maternal mortality and morbidity.

The incidence of obstructed labour and its complications have been minimized in the developed countries because of good nutritional status, facilities for transport and communication, wide spread health coverage and availability of trained health personnel along with optional...
utilization of antepartum and intrapartum care\textsuperscript{15}. Globally, approximately 80% of maternal deaths are due to direct obstetric complications like primary hemorrhage, sepsis, pre-eclampsia, eclampsia and obstructed labour\textsuperscript{16}. Together with hemorrhage, infection, hypertensive disorder of pregnancy, obstructed labour is a major cause of prenatal and maternal mortality and morbidity in developing countries\textsuperscript{17}. More than 529000 women die every year from pregnancy related complication and more than 99% of these deaths take place in the developing countries\textsuperscript{18}. The common cause of obstructed labour are cephalopelvic disproportion, malposition and malpresentation. The most important maternal morbidities are postpartum hemorrhage, wound infection, puerperal sepsis, abdominal distension, ruptured uterus as well as VVF. Fetal outcomes are still birth, asphyxia, neonatal jaundice and umblical sepsis.

The purpose of the present study was to determine the risk factors, socio-demographic factors as well as outcome of obstructed labour. Due to poor transport facilities most of the patients were brought late in morbid state.

\textbf{Methodology}

This cross-sectional study was carried out from January 2007 to December 2007 in the Department of Gynecology & Obstetrics at Shaheed Ziaur Rahman Medical College Hospital, Bogra. Shaheed Ziaur Rahman Medical College is a tertiary care hospital where cases are referred from upazilla as well as private clinics. After obtaining written informed consent patients with features of obstructed labour were enrolled consecutively in this study. Both prime and multi-gravida patients admitted with obstructed labour or developing this condition after admission were included. Patients having hypertension, convulsion or other medical diseases were excluded. A detailed history including obstetric history, socio-demographic history, any medical disease, details of intrapartum events were recorded. Demographic factors like age, socio-economic condition, educational status and obstetrical history like parity, previous mode of delivery and previous outcome of baby were recorded. During admission, the general condition of mothers were assessed as well as the fetal lie, presentation, position and heart sound were recorded. Pelvic examination was carried out to assess the cervical dilatation, state of liquor amni, position, presentation, pelvic assessment, degree of caput, moulding, uterine rupture. Destructive operations included craniotomy was done in dead fetus with cephalic presentation with full cervical dilatation. APGAR score at 5 minutes of 7 and above was taken as normal while scores less than 7 was taken as birth asphyxia. Condition of the patient, preoperative and postoperative findings, mode of delivery, associated complication (both mother and fetus) were recorded. At post partum period data regarding maternal outcome were recorded which included abdominal distension, postpartum hemorrhage, foul smelling discharge, fever, character of wound, burring micturition, urinary incontinence. Fetal condition was evaluated by the nature of feeding, development of jaundice, umbilical condition, features of neonatal infection. The statistical analysis was done in SPSS version 17.

\textbf{Results}

The total number of 3171 deliveries was occurred during this study period of which obstructed labour was accounted for 132 cases and was given an incidence of 4.2%. The highest frequency was found among the 25-30 years of age group (21.9%) and the least frequency among those >35 years. The mean age was 24+5.41 years, 46.7% case was unbooked and 52.4% had primary education only. The highest frequency (52.%) was found among the primigravida while the least was among the multigravida (table 1).

The commonest cause of obstructed labour was cephalopelvic disproportion (44.8%) followed by malposition (persistent occipito-posterior) (25.7%), malpresentation mostly shoulder presentation (10.5%) and breech presentation (9.5%). Fetal abnormality was found mostly severe hydrocephalous (2.8%) (Table 2).

Majority of the patients were delivered by caesarean section (78.1%) followed by craniotomy (16.1%). Caesarean hysterectomy was performed for 3(2.9%) cases out of which two cases for ruptured uterus, 1 case for postpartum hemorrhage. Repair of ruptured uterus was done for 3(2.9%) cases out of which 2 cases for scar rupture (Table 3).

Discussion
In this study obstructed labour accounted for 4.2% hospital delivered within the range reported for other developed countries. In India19 its incidence was found 2.5%. In Eastern Nigeria20 study over a period of 5 years revealed the incidence was 4.7%. This incidence of this study is reflective of overall health system, educational status, poverty, lake of vigilant of obstetric care, delayed referral and poor facilities for transport of patients from remote area.

Mostly obstructed labour occurred in nonbooked, primigravida, patient from rural area and those belonging to poor class, illiterate or having primary education. Health education is suggested. Specially for primigravida whose pelvis has not been tested.

Women who are educated likely to be economically and socially, empowered to break socio-culture and financial barrier. Duration of labour is the important factor that is significantly associated with maternal and perinatal mortality. In this study the most common cause of obstructed labour was cephalo-pelvic disproportion followed by mal-presentation and mal-position, which was relevant to other studies2,3. In grand multipara however malpresentation is suggested. Specially for primigravida whose pelvis has not been tested.

The common mode of delivery was LUCS because of its safety. Although some still superior to LUCS in moribund cases; however studies have shown that the use of regional anesthesia has made LUCS to be safe and its outcome to be comparable to that of destructive operation in moribund cases1. Among the destructive operation only craniotomy was done as it was easier to perform.

The risk of developing complication with either LUCS or
destructive operation was not statistically significant which showed that either method of relieving obstruction have favorable outcome in this tertiary care centre because of advent of new generation of antibiotics, better surgical method, anesthetic facilities, good pre-operative and post operative care which has made LUCS safe. Patients before discharge were counseled to book early in subsequent pregnancies and deliver in well established health care facilities where adequate monitoring are available with facilities for caesarean section.

Regarding complications of obstructed labour abdominal distension was the most common complication followed by urinary tract infection, puerperal sepsis post partum hemorrhage. Rupture uterus is the common sequellae of obstructed labour[9]. In this 5.8% cases were ruptured uterus. This was due to referral of very mismanaged patient. This study has shown that uterine rupture was uncommon among the primigravida as primigravid uterus meets obstructed labour with inertia whereas multigravid uterus meets obstruction with hypertonic uterine contraction. Urinary tract infection was due to prolonged catheterization. Maternal mortality and morbidity was 52.2% because of prolonged rupture. This was due to referral of very mismanaged patient. This study has shown that uterine rupture was uncommon among the primigravida as primigravid uterus meets obstructed labour with inertia whereas multigravid uterus meets obstruction with hypertonic uterine contraction. Urinary tract infection was due to prolonged catheterization. Maternal mortality rate was about 1% in this study which is lower than that of other developing countries[1-10] because of meticulous care. In this study maternal death occurred due to extensive rupture.

Vesico-vaginal fistula is a well known late sequel of obstructed labour superscript[1]. In this study VVP was developed 1.9% cases. The poor fetal outcome with perinatal mortality and morbidity was 52.2% because of prolonged labour, neonatal sepsis from multiple unsterile vaginal examination before attended 10 hospitals which is similar to other studies[18-20]. Obstructed labour can be prevented by providing optimal obstetric care, good nutritional support as nutrition is essential for normal pelvis[3]; however it takes long time to attain the goal. Another important potential intervention for prevention of obstructed labour was antenatal care coverage. In this study overall antenatal coverage was 18.1%.

The strength of this study is that a proper predesigned questionnaires has been made for collecting data, better surgical method, good pre-operative and post operative care. Information regarding the duration of labour was not satisfactory as labour at home and attended by untrained dais.

In the absence of sophisticated fetal and maternal monitoring devices cases were evaluated clinically. The uterine activity measurement was not possible and assessment of severity of fetal distress sometimes was not accurate.

Conclusion
In this study the commonest cause of obstructed labour is the cephalopelvic disproportion, malposition and malpresentation of which shoulder presentation & breech presentation are the most common. Severe hydrocephalus is the most common fetal abnormality found in this study. To decrease these unfortunate and mostly preventable obstetrics complications, restructuring to MCH service should be done with particular attention to increase the community awareness, decentralization to maternity service, effective health care and effective referral system.
