Antithyroid antibody (TPO-Ab) Status in Type 2 Diabetic Patients

Kamrunnahar Alo¹, Safayet Ahammed², Mahboba Rahman¹, Shyamal Chandra Banik³, Kazi Shihab Uddin⁴.

Abstract
Background: The presence of thyroid peroxidase antibody (TPO-Ab) in type 2 diabetic patients is a risk factor for the future development of thyroid dysfunction.

Objective: To observe thyroid antibody status in type 2 diabetic patients.

Materials and Methods: This cross-sectional study was carried out in the Department of Physiology, Sir Salimullah Medical College, Dhaka from July 2016 to June 2017. Total 60 subjects including male and females, age ranged from 40 to 60 years were included in this study, among them 30 were non-diabetic subjects and 30 were type 2 diabetic patients.

Results: In this study, the mean serum TPO-Ab level was significantly (<0.01) higher in diabetic subjects in comparison to that of apparently healthy non-diabetic subjects and mean serum TPO-Ab level was higher in uncontrolled diabetic subjects in comparison to that of controlled diabetic subjects but the difference is not statistically significant. However, On the other hand, among the diabetic patients, 6.67% had positive TPO-Ab whereas, among the uncontrolled diabetic patients 11.76% had positive TPO-Ab. There was no correlation between TPO-Ab and HbA1c.

Conclusion: The present study reveals that TPO-Ab may present in type 2 diabetic patients.

Key words: TPO-Ab, Type 2 diabetes mellitus.

Introduction
Diabetes is a chronic, metabolic disease characterized by elevated levels of blood glucose (or blood sugar), which leads over time to serious damage to the heart, blood vessels, eyes, kidneys and nerves. The most common is type 2 diabetes, usually in adults, which occurs when the body becomes resistant to insulin or doesn't make enough insulin.¹ In the past few decades the prevalence of type 2 diabetes has risen dramatically in countries of all income levels due to population growth, aging, urbanization, increase prevalence of obesity and physical inactivity.² Type 1 diabetes, once known as juvenile diabetes or insulin-dependent diabetes, is a chronic condition in which the pancreas produces little or no insulin by itself. Long term diabetes mellitus is associated with vascular complications like retinopathy, nephropathy, peripheral and autonomic neuropathy, cardiovascular and cerebrovascular diseases.³ In addition, thyroid dysfunction is another common endocrine disorder that is also increasing day by day⁴ and may occur in diabetic patients⁵ especially those with autoimmune thyroid disorder.⁶ Thyroid peroxidase (TPO) is an important enzyme that helps in synthesis of thyroid hormones catalyzing the oxidation of iodide on tyrosine residues in thyroglobulin.⁹ TPO is a membrane-associated hemo-glycoprotein expressed only in thyrocytes and is one of the most important thyroid gland antigens. Presence of antibody against this antigen is known as TPO antibody.¹⁰ Genetic and environmental factors are involved in the pathogenesis of autoimmune thyroid disease (AITD).¹¹ However, the prevalence of TPO antibody in general population is 21.85%⁵ whereas in type 2 diabetic patients it is about 36.7%.¹² Kahaly found that, in areas of the world where iodine intake is sufficient, autoimmune disorders represent the commonest cause of thyroid dysfunction.¹³ Sahu et al. (2015) found 28.33% thyroid dysfunction in type 2 diabetic patients. TPO antibody was positive in 62.07% cases of hypothyroidism and 40% cases of hyperthyroidism. They also observed that TSH showed significant positive correlation with TPO antibody. They had significant negative correlation between TSH and fasting serum insulin, HOMA-IR, HOMA-B.³ Due to the increased prevalence of thyroid dysfunction in type 2 diabetes and antibody may be one of the factors,¹⁴ this study was conducted to investigate thyroid autoimmunity in type 2 diabetes. Sarfo kanta states that, the presence of thyroid autoimmunity can increase risk of subclinical thyroid disease significantly and in their study they
found higher frequency of thyroid autoimmunity in Ghanaian type 2 diabetic patients and significant association with thyroid dysfunction, female gender, hypercholesterolemia and hyperglycemia.\textsuperscript{15}

Galag et al (2016) suggested that, all the subjects with type 2 diabetic patients particularly those with positive antibody should measure TSH level yearly to detect asymptomatic thyroid dysfunction.\textsuperscript{16} As, it can aggravate classical risk factors such as dislipidaemia and lead to an increased risk of cardiovascular events, nephropathy and peripheral vascular disease in these patients.\textsuperscript{17,18}

\textbf{Materials and Methods}

This cross sectional study was carried out in the Department of Physiology, Sir Salimullah Medical College (SSMC), Dhaka from July 2016 to June 2017. The study protocol was approved by Institutional Ethics Committee of SSMC. For this study, 30 diagnosed type 2 diabetic patients (Group-B) age ranged from 40 to 60 years were selected from the Out Patient Department (OPD) of Endocrinology, Sir Salimullah Medical College and Mitford Hospital, Dhaka. They were diagnosed previously according to American Diabetic Association (ADA) criteria. Thirty apparently healthy subjects with similar age, BMI and socioeconomic status were selected as comparison (Group A). Study group was again subdivided into two groups according to HbA1c level. Group B1 included 17 uncontrolled diabetic patients and Group B2 included 13 controlled diabetic patients. Diabetic patients with renal disease, known thyroid abnormalities, any other endocrine abnormalities and pregnancy were excluded from this study. All the subjects belonged to middle socio-economic status. After selection, the subjects were thoroughly informed about the aim, objectives and procedure of the study and were encouraged for voluntary participation. An informed written consent was taken from each subject. Detail personal, medical, family, socio-economic, occupational histories were taken and thorough physical examination was done and all informations were recorded in a standard pre-fixed questionnaire. With all aseptic precautions 7 ml of venous blood was drawn by sterile disposable syringe from ante-cubital vein. Then 2 ml of whole blood was transferred to an EDTA tube for determination of HbA1c level. The remaining blood was transferred to a clean and dry glass test tube and was kept in slanted position till formation of clot. After centrifugation, supernatant serum was collected in labeled eppendorf test-tube and was used for different biochemical tests. For assessment of antibody status, serum TPO antibody level was measured by chemiluminescent microparticle immunoassay method in the Department of Biochemistry, Bangabandhu Sheikh Mujib Medical University, Dhaka. However, fasting plasma glucose level was estimated by glucose oxidase method in the Department of Physiology, Sir Salimullah Medical College and HbA1c level was estimated by ion exchange high performance liquid chromatography method in the Department of Biochemistry, BSMMU to observe their glycemic status. Data was expressed as mean ± SD (Standard Deviation). The statistical analysis was done by Unpaired ‘t’ test and Bonferroni test by using Statistical Package of Social Science (SPSS) windows version-22. p value ≤ 0.05 was considered as significant.

\textbf{Results}

In this study, the mean (±SD) fasting blood glucose and HbA1c levels were significantly (p<0.001) higher in group B in comparison to those of group A. Again, the mean (±SD) serum TPO-Ab level was significantly (p<0.01) higher in group B in comparison to that of group A. (Table-I)

On the other hand, The mean (±SD) fasting blood glucose and HbA1c levels were significantly higher in group B1 (p<0.001) in comparison to that of group B2. The mean (±SD) serum TPO-Ab levels was higher in group B1 in comparison to that of group B2 but they are not statistically significant. (Table-II)

N= Total number of subjects
Discussion

This study observed thyroid autoimmunity in type 2 diabetic patients by measuring thyroid peroxidase antibody level. HbA1c level was also estimated to find out TPO-Ab level on uncontrolled and controlled diabetic patients.

In this study, the mean serum TPO-Ab level was significantly (p<0.01) higher in diabetic patients in comparison to that of non-diabetic subjects. But there was no significant difference on TPO-Ab level between uncontrolled and controlled diabetic patients. Almost similar findings were also reported by some other researchers of different countries.19,20,21

In this study, among the diabetic patients, 6.67% had positive TPO-Ab and 93.33% had negative TPO-Ab. Again, among the uncontrolled diabetic patients, 11.76% had positive TPO-Ab and 88.24% had negative TPO-Ab. All the controlled diabetic patients had negative TPO-Ab.

Data were expressed as mean ± SD. For statistical analysis, Bonferroni test was performed for comparison between two groups.

**Group B1**: Uncontrolled diabetic patients

**Group B2**: Controlled diabetic patients

*** = Significant at p<0.001, ns= not significant

n= Total number of diabetic subjects

In this study, among the diabetic patients, 6.67% had positive TPO-Ab and 93.33% had negative TPO-Ab. Again, among the uncontrolled diabetic patients, 11.76% had positive TPO-Ab and 88.24% had negative TPO-Ab. All the controlled diabetic patients had negative TPO-Ab.
Conclusion
From this study it can be concluded that, TPO-Ab level is increasing in type 2 diabetic patients and early detection may prevent future development of thyroid dysfunction in type 2 diabetic patients.

Acknowledgement
We are grateful to all the faculty members of Department of Physiology, Sir Salimullah Medical College for their immense support and special thanks to all the subjects for their kind cooperation.
