Abstract:

The retrospective cross sectional study was undertaken to determine the pattern and different methods of treatment of mandible fractures. Four hundred and thirty five patients with mandibular fractures were treated during the year 2014-2015. Among the patients attended with facial trauma during mentioned period at casualty department of Dhaka Dental College hospital with the mandible fracture not associated with others facial bone fracture who were managed in this department and whose clinical record file are available in our record book were included in this study. A review of patients’ records and radiographs was conducted. Data regarding age, gender, cause of fracture, anatomic site and treatment modalities were reviewed. Data were presented by table and diagram. Age, location of fracture in table form, gender distribution, treatment in pie chart, etiology of fracture by histogram. There was higher prevalence in male (3.9:1), with occurrence peak between 21-30 years. The principal causes of fracture in this study were RTA (Road Traffic Accidents) representing 54.02 % (n=235), followed by physical assault 17.24% (n=75), Fall, Sports injury, Blow by heavy objects, Tube well injury & others. The most injured sites were in decreasing order parasymphysis (26.31%) followed by angle of mandible 17.89% then symphysis, condyle, body of mandible dentoalveolar, ramus, coronoid process of mandible. Most patients of mandibular fractures were treated by closed reduction (arch bar, arch bars with intermaxillary fixation IMF, eyelet wiring & lateral compression plate). Rest of the patients were treated with open reduction ( miniplates fixation, 3D plate fixation). Only 8.05% patients were managed by conservative approach. This study reflects patterns of mandibular fracture within the community and discuss various methods of mandible fracture management in the department of Maxillofacial casualty in Dhaka dental college hospital. It is hoped that assessment presented here will be valuable to government agencies and health care professionals involved in planning future programs of prevention & treatment of mandible fracture.

Key words: Mandible fracture, Pattern & management, Maxillofacial casualty, RTA (Road Traffic Accident)

Introduction:
The mandible is the area of the face with major incidence of fracture. Its prominence and position in the skeletal face predispose to frequent traumas. Mandible is the second most commonly fractured bone after nasal bone, though it is the largest and strongest facial bone. Mandibular fractures can involve only one site or can often involve multiple anatomic sites simultaneously. The etiology and pattern of mandibular fracture vary considerably among different study populations. Recent overall shift in the mechanism of injury and age distribution of patients sustaining these injuries are well-documented. There is reported variability in the pattern of mandibular fractures resulting from different causes of injury, such as road traffic accidents (RTA), assaults, and falls. Increased frequencies of RTA and domestic violence have emerged as the etiological factors in mandibular fractures in developing countries like India. Furthermore, there is an increase in the proportion of adolescent and young adults sustaining these injuries. Mandible fractures may lead to deformities be them by displacement or non restored bone losses with dental occlusion affection or temporomandibular joint disorder. If not identified or inappropriately treated, these lesions may lead to severe squels, both cosmetic and functional.

It has been reported that fractures of the mandible account for 36% to 59% of all maxillofacial fracture. The large variability in reported prevalence is due to a variety of contributing factors such as gender, age, environment and socio-economic status of patient as well as the mechanism of the injury. The most favorable site of fracture (in descending order) in mandible are the body, angle, condylar region, symphysis, and coronoid process. Treatment of mandibular fractures has changed over the last 20 years. There has been a decrease in the use of wire osteosynthesis and intermaxillary fixation and an increase in preference for open reduction and internal fixation with miniplates. This has helped to reduce malocclusion, non-union, improved mouth opening, speech, oral hygiene, decrease loss and the ability for patients to return to work earlier. The aim of the study was to examine the pattern and treatment of mandibular fractures. A clearer understanding of pattern of mandibular fractures will assist health care providers as they plan and manage the treatment of traumatic maxillofacial injuries. Such information can also be used to guide the future funding of public health programmer geared toward prevention.

Methodology:
The retrospective cross sectional study was undertaken at casualty Department of Dhaka Dental College & Hospital during period of January 2014 to December 2015 to determine the pattern and different methods of treatment of mandible fractures. Four hundred and thirty five patients with mandibular fractures were treated during the year 2014-2015. A review of patient’s records and radiographs was conducted. Data regarding age, gender, cause of fracture, anatomic site and treatment modalities were reviewed.

Results:
In the studied period, mandibular fractures were diagnosed in 435 patient’s data regarding age, gender, cause of fracture, anatomic site and treatment modalities were reviewed. There was higher prevalence in male (3.9:1), (Figure-1)

Figure 1: Gender distribution of the respondents (n=435)

Figure illustrates the sex distribution of the respondents. Out of 435 patients 345 (79%) were male and 90 (21%) were female respondents. Males were predominant.

Age incidence was peak between 21-30 years. (Figure-2)

Figure shows site wise distribution of mandibular fractures.

Most patients of mandibular fractures were treated by closed reduction (arch bar, arch bars with intermaxillary fixation IMF, eyelet wiring & lateral compression plate)70.11% & 21.83% of patients were treated with open reduction ( miniplates fixation. 3D plate fixation). Only 8.05% patients were managed by conservative approach.

**Discussion:**

All over the world, maxillo-facial injuries have continued to generate discussion among researchers, due to the functional and cosmetic deformities affecting the victims. The etiological factors and pattern of maxillo-facial injuries have been reported to vary from one geographical area to another, depending on the
socioeconomic status, geographic condition and cultural characteristics. Despite the fact that it is the heaviest and strongest facial bone, the mandible is prone to fractures for some specific reason: 1) it is an open arch; 2) it is located in the lower portion of the face; 3) it is the mechanism of hyperextension and hyperflexion of the head in traffic accidents; 4) it gets atrophy as a result of aging.\(^8\)

The results of this study of mandibular fracture coincide with previous reports, particularly regarding age and sex of patients.\(^2\) In our study, the highest incidence of mandibular fractures is found in the age group of 21–30 years (26.89%). The possible reasons for this in our geographic area may be very high use of two-wheelers, early bikers, lack of safety measures in the form of helmets and improper road conditions, as most of fractures in this group belong to RTAs.\(^2\)

There was higher prevalence in male (3.9:1). The male predominance observed in our study was in harmony with other reports around the world which shows male: female (3:1).\(^10\) Males are more exposed due to their more frequent participation in high risk activities, such as driving vehicles, sports that involve physical contact, an active social life, drugs and alcohol habits, etc.\(^10\)

The principal causes of fracture in this study were RTA (Road Traffic Accidents) representing 54.02%(n=235), followed by Physical assault 17.24% (n=75), Fall, Sports injury, Blow by heavy objects, Tube well injury & others. There is a stark difference in the etiology of maxillofacial trauma in developing and developed nations. The common cause of maxillofacial trauma in developing countries is RTAs, while assault is the most common cause in developed countries. Our findings also support the same, as 68% of our patients; RTA was the cause of injury.\(^2\)

These etiological differences reflect differences in the socio-economic factors, national infrastructure development (particularly roadways, traffic regulations and legislation) and other behavioral habits, such as alcohol consumption or criminal activities. The high number of maxillo-facial injuries attributed to RTA is explained by an inadequate road safety awareness; unsuitable road conditions.\(^2\)

The most common site of fracture in mandible evidenced by the present investigation was the parasymphyseal (26.31%), which is consistent with the findings of King et al., who established a statistical significance between road traffic accidents and parasymphysis fractures. Atanasov\(^12\) and Wong\(^13\) reported that motorcycle accidents (79.5%) were the major cause of mandible fractures, with the parasymphysis as the most common site. Sunita Malik et al.\(^14\) also found parasymphysis as the most common site of fracture in the mandible. Causes of RTA is explained by unsuitable road conditions without expansion of motorworks; violation of speed limit; old vehicles without safety features.\(^10\)

In present study mandibular angle fractures were second most common 17.89%. However, Olson et al.\(^15\) showed that there was a higher incidence of angle involvement in patients with mandibular trauma.\(^2\) However, our study was not consistent with the findings of Adekeye, Nair\(^17\) and Adevaya\(^18\), who reported the body as the most prominent site, whereas Van Beek\(^19\) found the condyle as the most common site.\(^10\) It is difficult to cite a reason for this difference; perhaps further study on the causes of the regional mandibular fractures would be useful. One can speculate that inter-population difference in the sites of mandibular fractures partly related to the diverse etiological factors involved.\(^8\)

Several treatments may be applied in maxillofacial fractures, the differences among them depending on many factors, such as costs, patient’s affordability, conditions in the hospital, doctor’s decision and skill, patient’s willingness to obey the treatment - all of them varying from one country to another. Most of the patients 70.11% treated in our hospital benefited from closed reduction with arch bar fixation, and only few of them had open reduction and internal fixation, which is consistent with the studies conducted by Kamulegeya et al.,\(^20\) Chandra\(^21\), Erol et al.,\(^22\) Kilasar et al.\(^23\) and Sunita Malik et al.\(^14\) Open reduction and internal fixation has been reported to be the “gold standard” of the treatment of maxillo-facial fractures.\(^10\)

In recent years, there has been a trend towards rigid fixation with miniplates. In our study 22 cases (21.83%) were treated with miniplates. The postoperative results were satisfactory. Most of the patients belong to low socio-economic status and absence of GA facility at causality department; a small number of patients(21.83%) selected for miniplate fixation under LA with conscious sedation.
Conclusions:
Road traffic accidents (RTA) represented the major etiological factor of maxillo-facial injuries, with young adult males as their main victims. The high number of trauma victims with maxillofacial injuries evidenced in the present study highlights the importance of the Dental Surgery unit, besides the other disciplines assuring an emergency management of trauma victims. This study also evidences the importance of cooperation and coordination among the various medical disciplines, for a rapid management of maxillo-facial injuries, and not only, which might prevent functional as well as aesthetic morbidity.
